Catskills Environmental Research & Monitoring  
2025 Conference  
22 Oct 2025

# Overview

## Purpose & Approach

---

- Objectives
- Approach

## Functions & Outputs

---

- Biomass & C Stocks
- Stock-Change
- Monitoring
- GHG Inventory
- Uncertainty

## Insights on Catskills

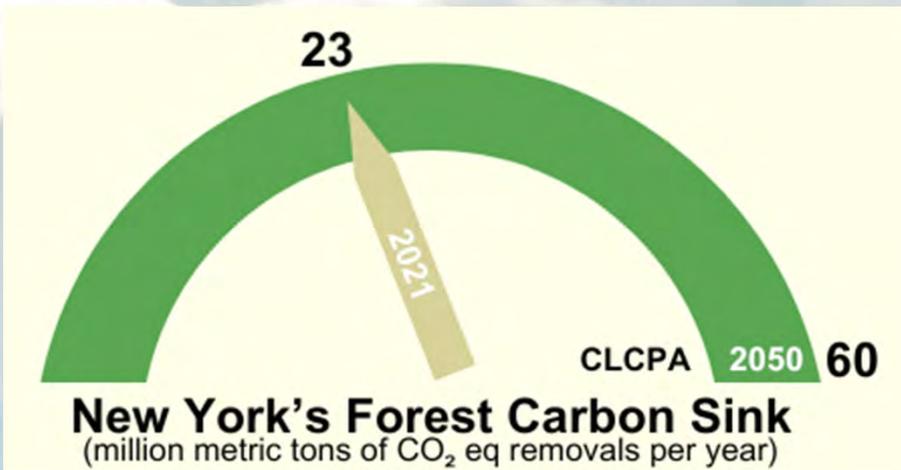

---

- C Stocks & Changes
- Catskills Park & FP Lands
- Role in NYS Forest C Sink
- 'Top Tier' Parcels

## Applications & Data Products

- Climate solutions planning
- Parcel-level MMRV
- NY Solar Scorecard
- 2024 NYS-wide update

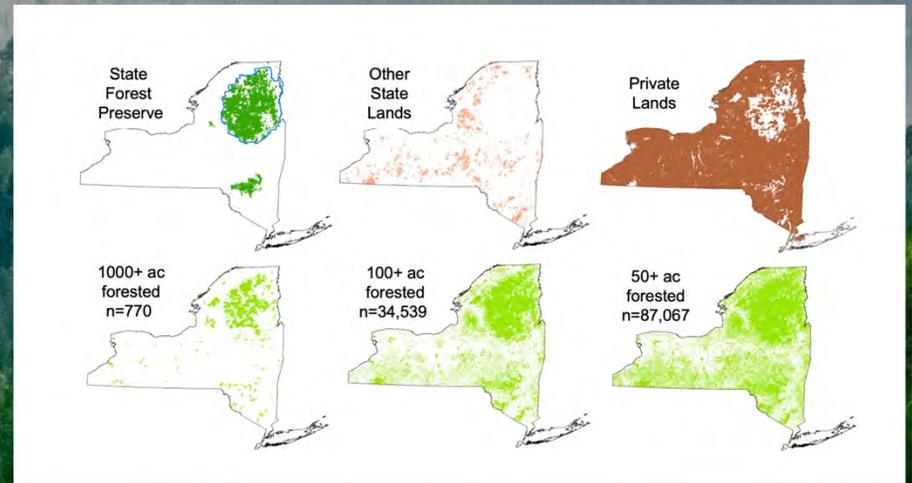

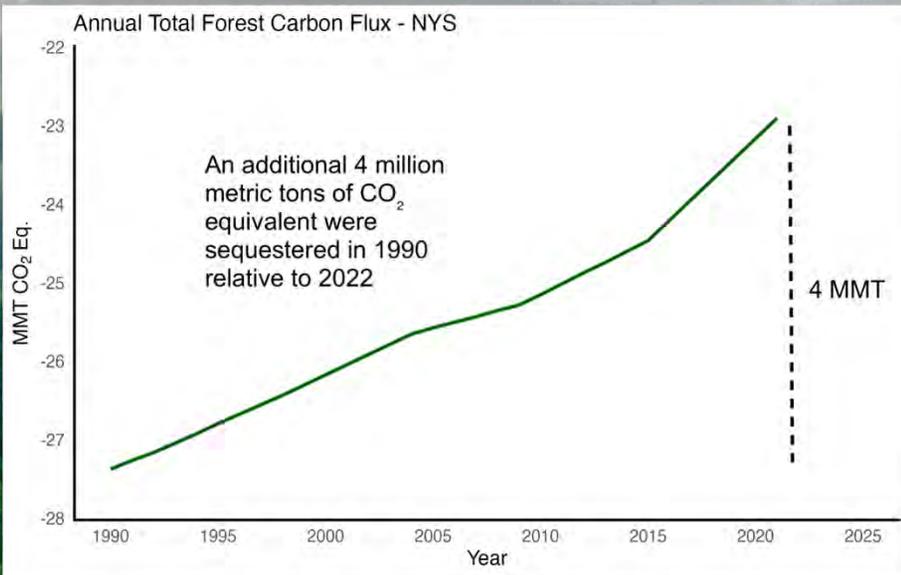

**Reforestation**  
Establish more forested land through passive and active measures

**Avoided Forest Conversion**  
Prevent conversion of existing forest lands to other land use types

**Natural Forest Management**  
Enhance carbon benefits on working forest lands and help forests adapt to changing environment

## New York

Table 349: Net CO<sub>2</sub> Flux from Forest Pools in Forest Land Remaining Forest Land (MMT CO<sub>2</sub> Eq.), New York

| Carbon Pool           | 1998   | 1999   | 2000   | 2001   | 2002   | 2003   | 2004   | 2005   | 2006   | 2007   | 2008   | 2009   | 2010   | 2011   | 2012   | 2013   | 2014   | 2015   | 2016   | 2017   | 2018   | 2019   |
|-----------------------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|

Notes: The forest ecosystem C stocks do not include trees on non-forest land (e.g., agriculture systems and wetland areas). Totals may not sum due to independent rounding. Population estimates compiled using FIA data are assumed to represent stocks as of January 1 of the inventory year. Plus is the net annual change in stock. Thus, an estimate of flux for 2019 requires estimates of C stocks for 2018 and 2020.

**Objective**

To translate FIA's stock-change methodology for forest GHG inventory into fine-resolution (30m, annual) maps and data for New York State

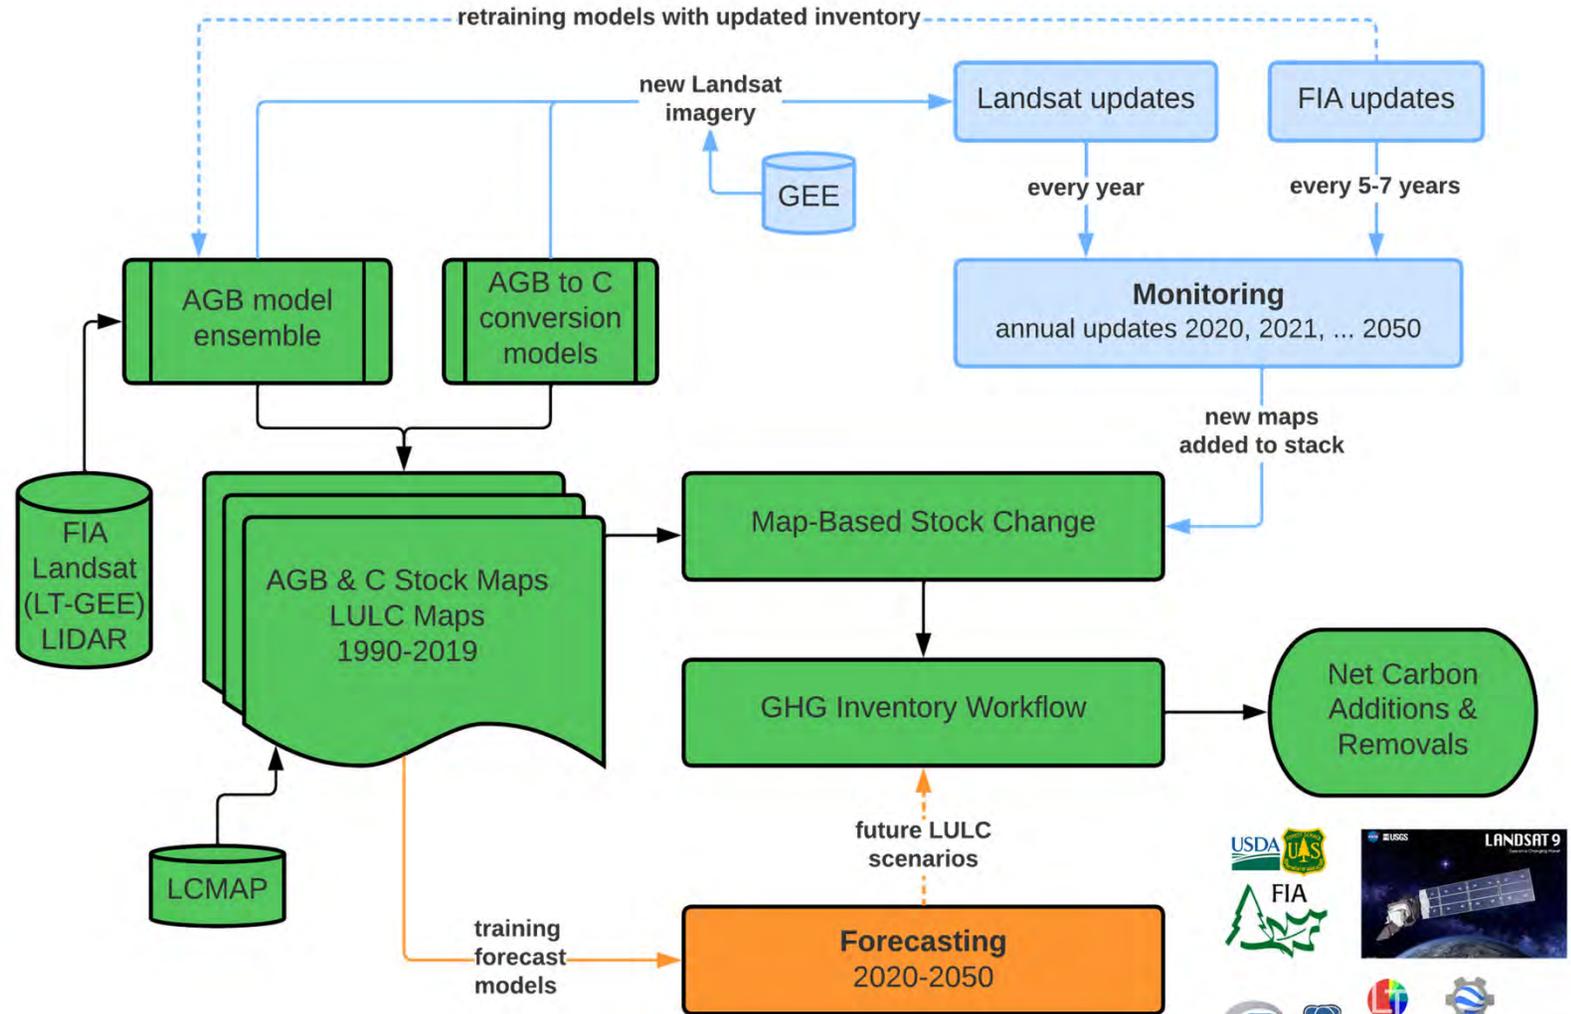

Integrated basis for

- **AGB & C Mapping**
- **Stock Change**
- **GHG Inventory**
- **Monitoring**
- **Forecasting**

Built on freely available data\* and open-source computational tools

# Framework

\*excludes FIA plot coordinates!

Train machine-learning models on systematic field inventory and existing leaf-off LIDAR

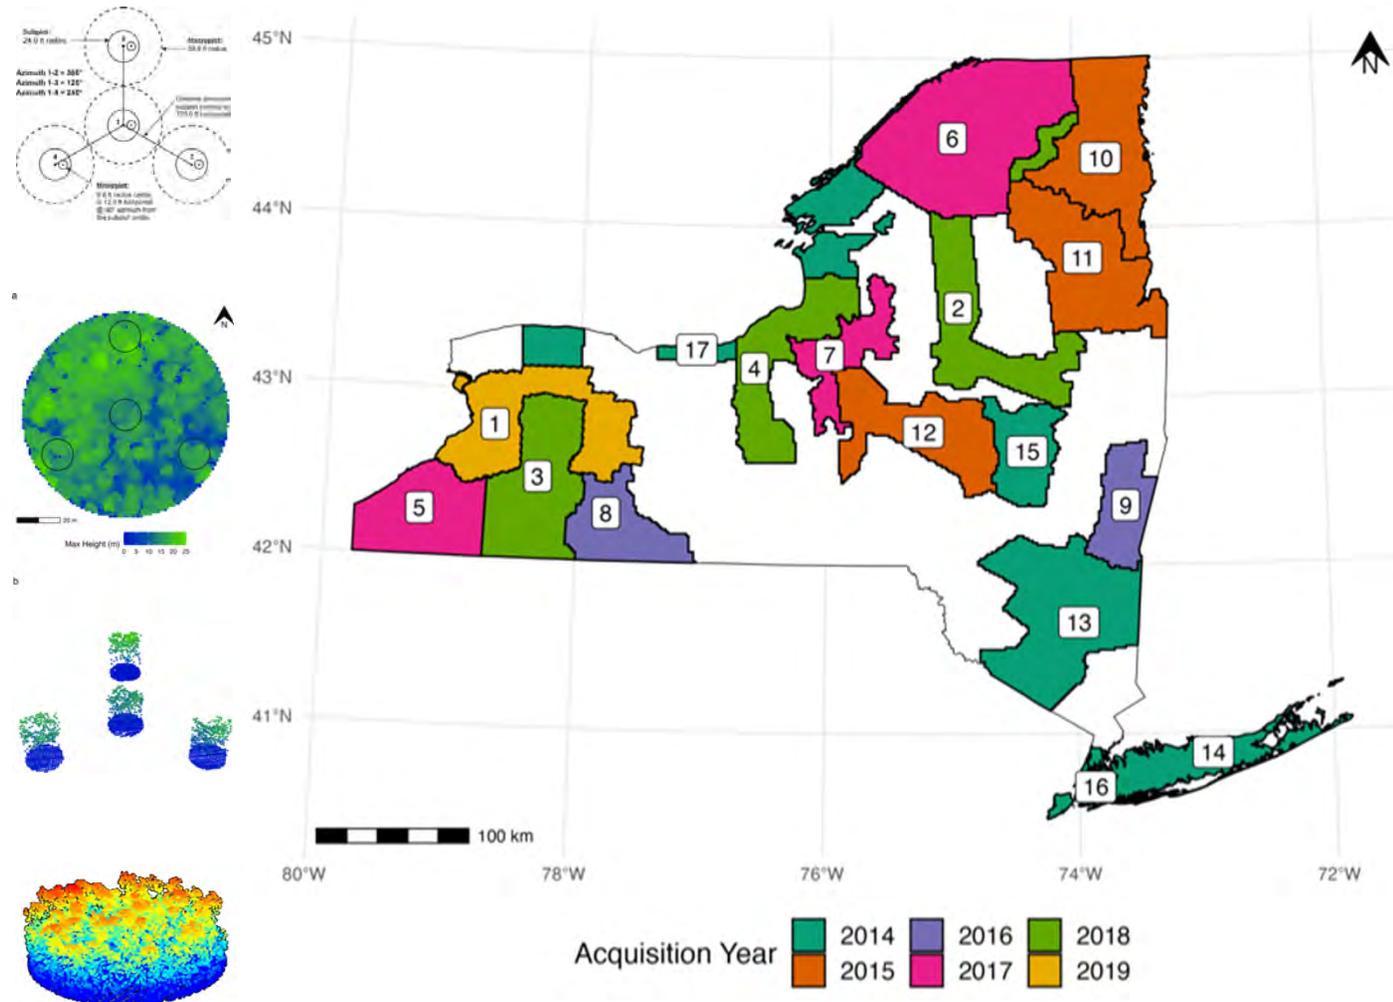

Airborne LIDAR available in a spatiotemporal patchwork

Aligning FIA plot inventory and LIDAR coverages to maximize model obs. was challenging

Predictors derived from LIDAR point clouds gridded to 30 m

Use ML models to map forest aboveground biomass (AGB) for LIDAR year at 30m resolution

## AGB & C Mapping

Trained Landsat-based models:

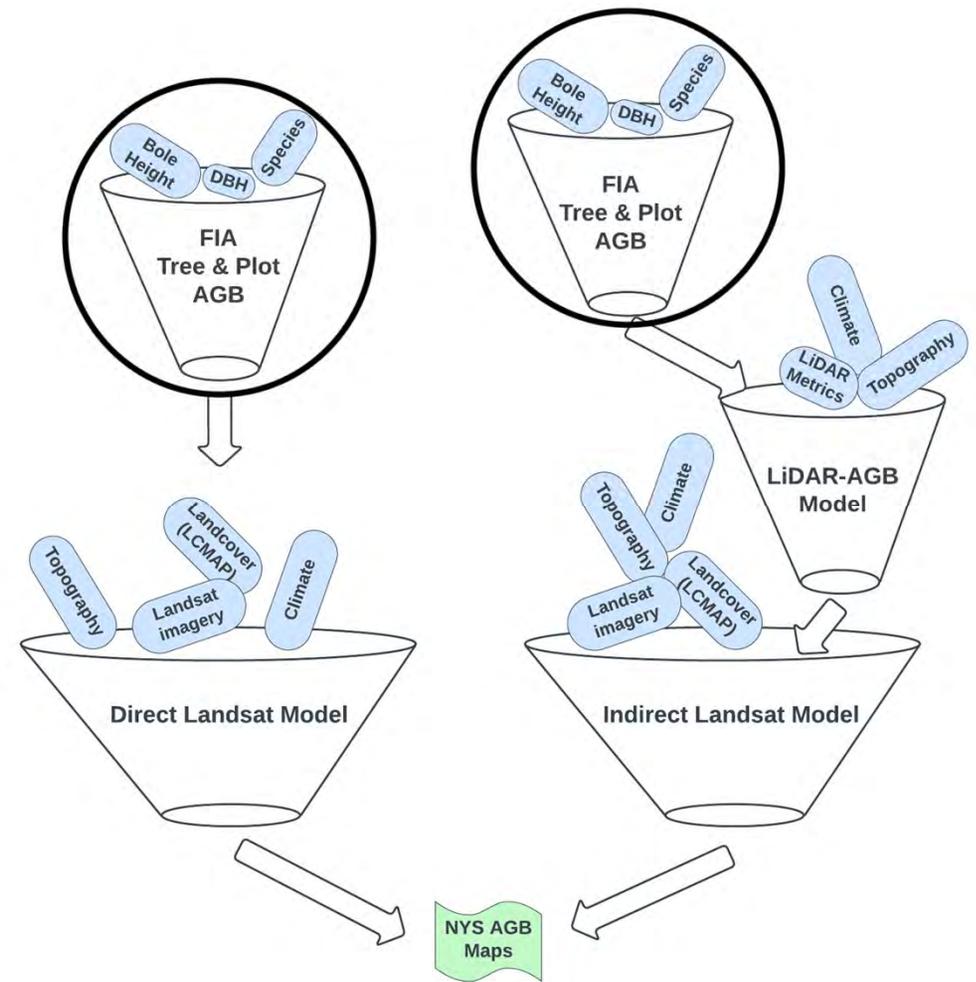

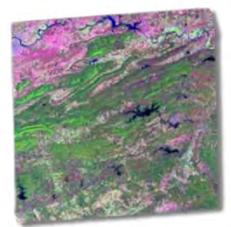

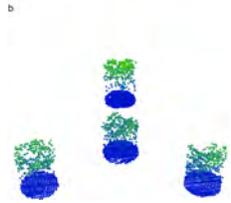

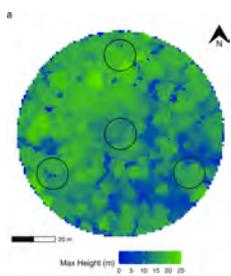

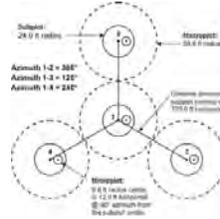

- Directly on FIA plots
- Indirectly on LIDAR-AGB prediction surfaces (maps)

AGB/C models typically have saturation thresholds: cannot predict above a ‘false ceiling’

- LIDAR ~300 Mg ha<sup>-1</sup> (<1% NYS)
- Landsat ~220 Mg ha<sup>-1</sup> (~4% NYS)

Training on LIDAR-AGB also improves fine-scale patterns

We combined models into an ensemble that has a prediction ceiling of ~280 Mg ha<sup>-1</sup> (<2% NYS)

# AGB & C Mapping

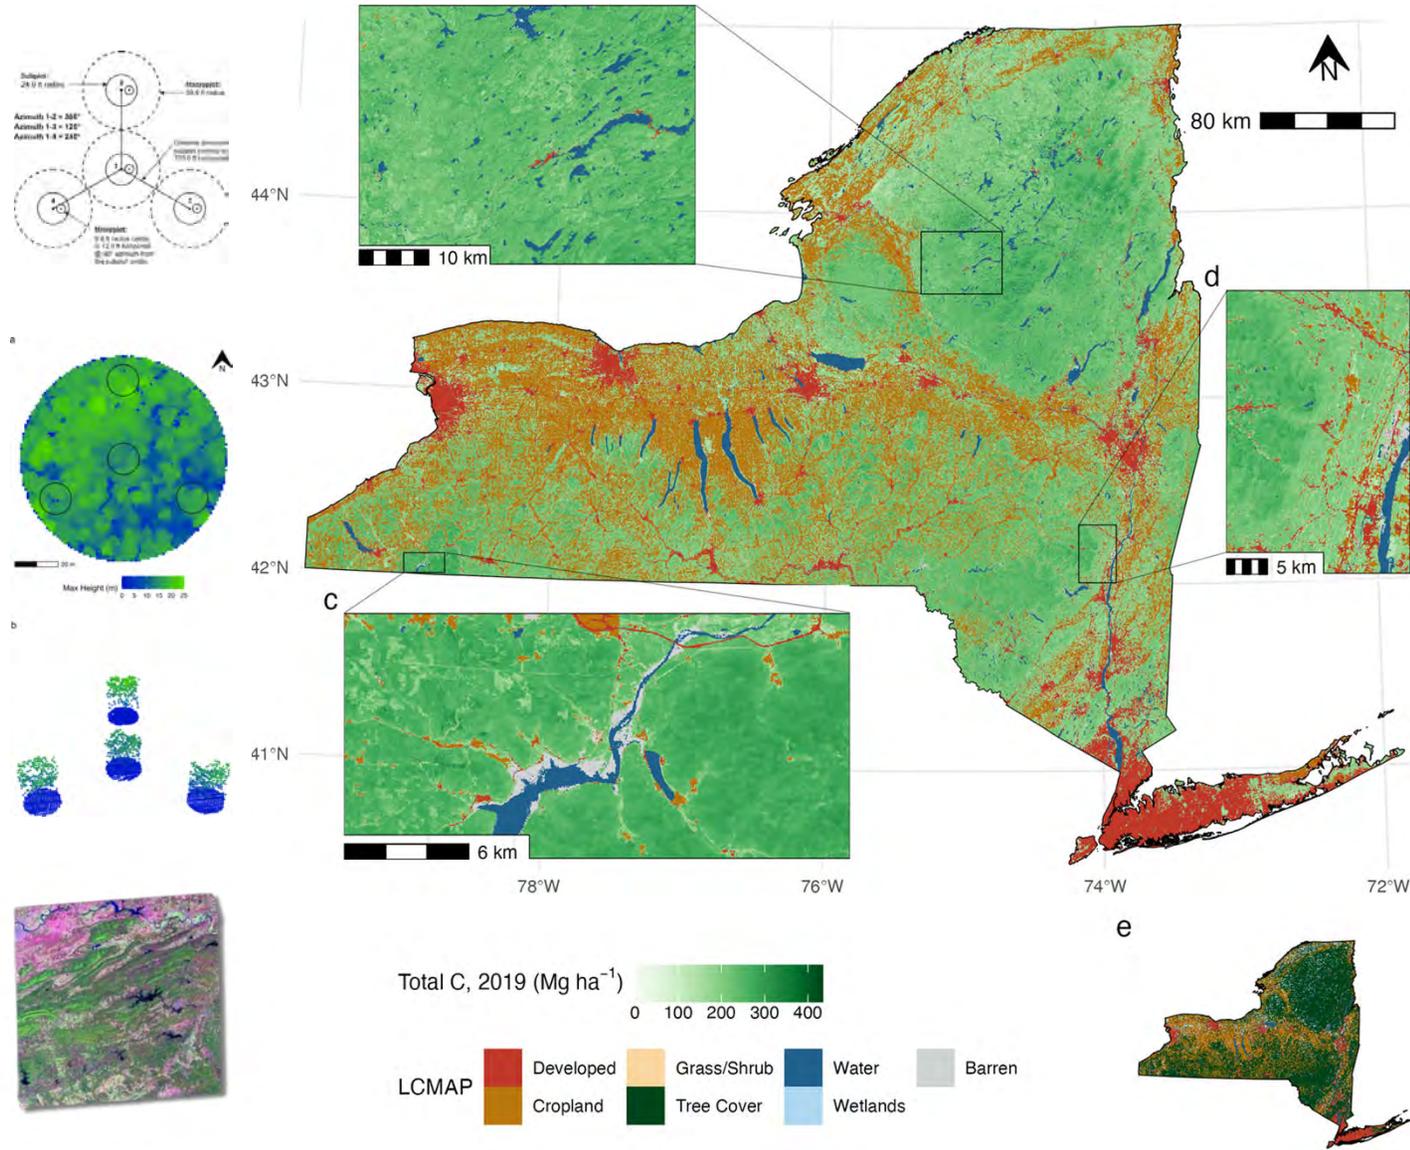

Ensemble machine-learning models, trained on FIA plots and EO data (LIDAR, Landsat, LT-GEE)

Version 1.x: 30m annual AGB maps from 1990 to 2019, AGB estimates converted to AGC, BGC pools.

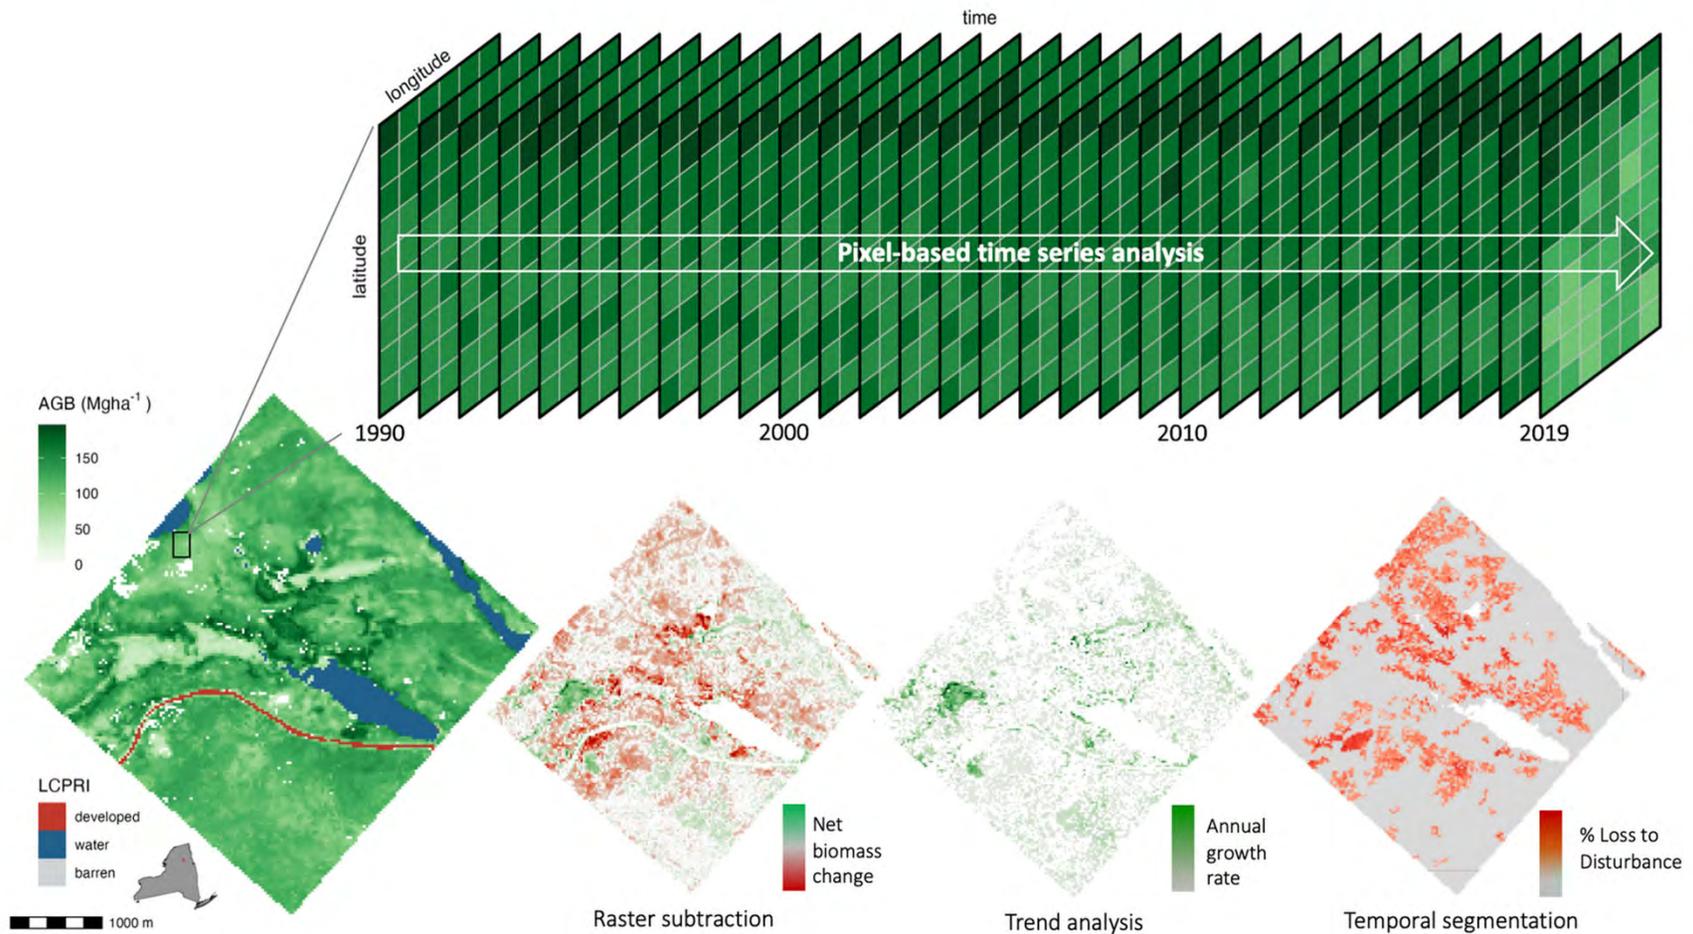

Version 2.0: AGB, AGC, BGC predictions based on FIA NSVB, LIDAR, Landsat-c2, 1990-2023

Soil, litter, deadwood C pools mapped using models trained on FIA Phase 3 and EO data

Annual statewide 30m maps of C pools for all forested lands

# AGB & C Mapping

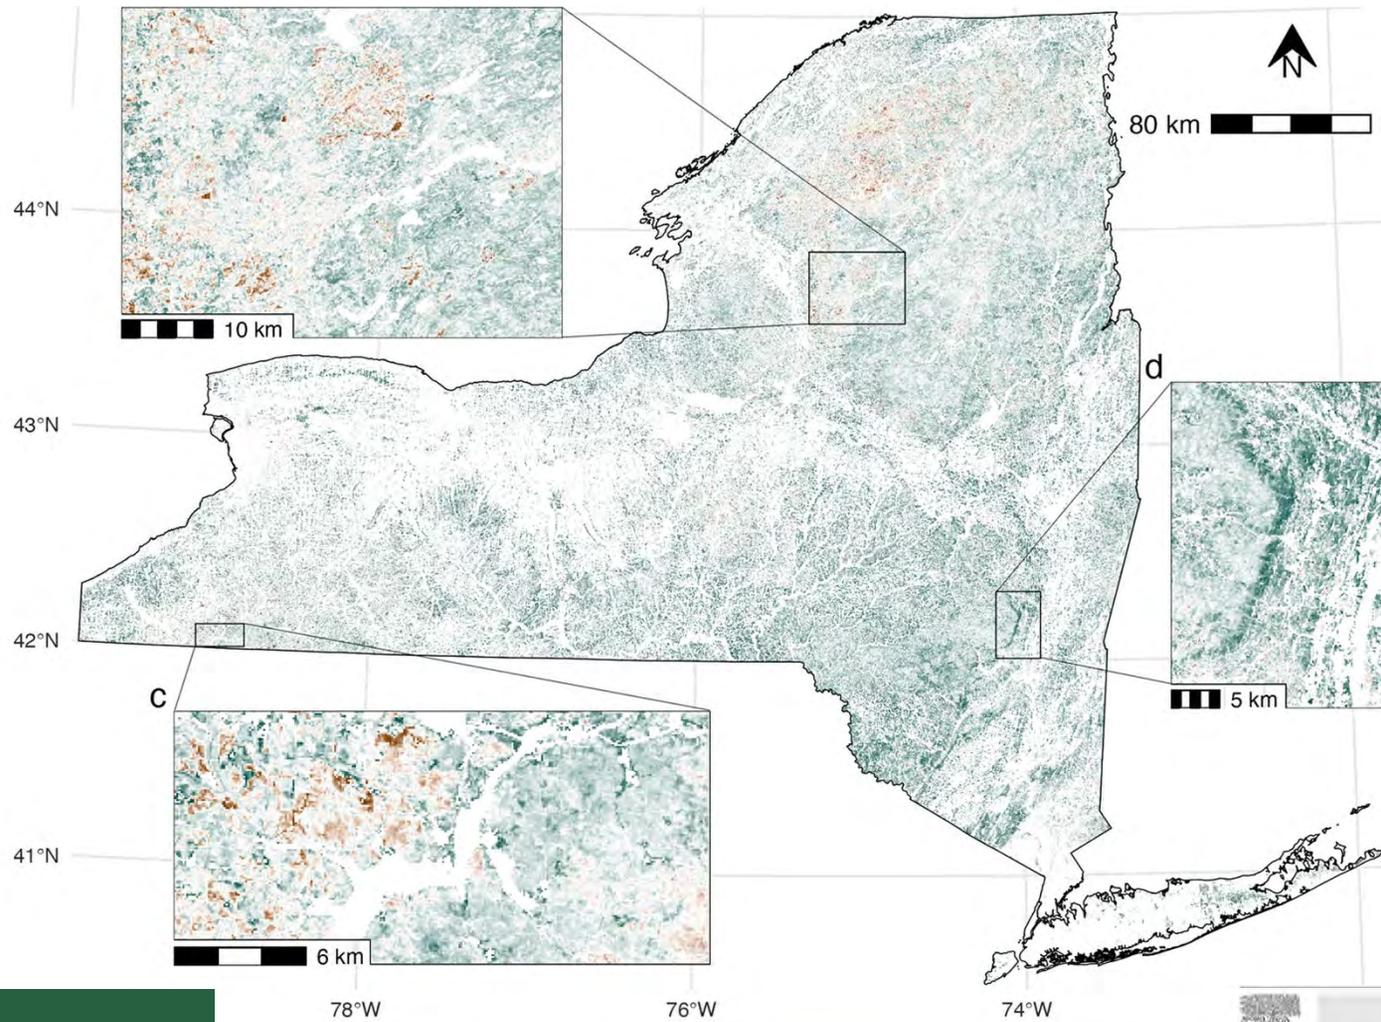

## Stock-Change

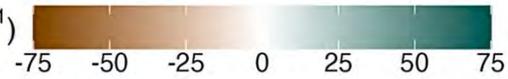

We compile 'raster stacks' of 30m annual AGB/C and LULC maps, providing a flexible basis for stock-change analysis using raster operations, such as:

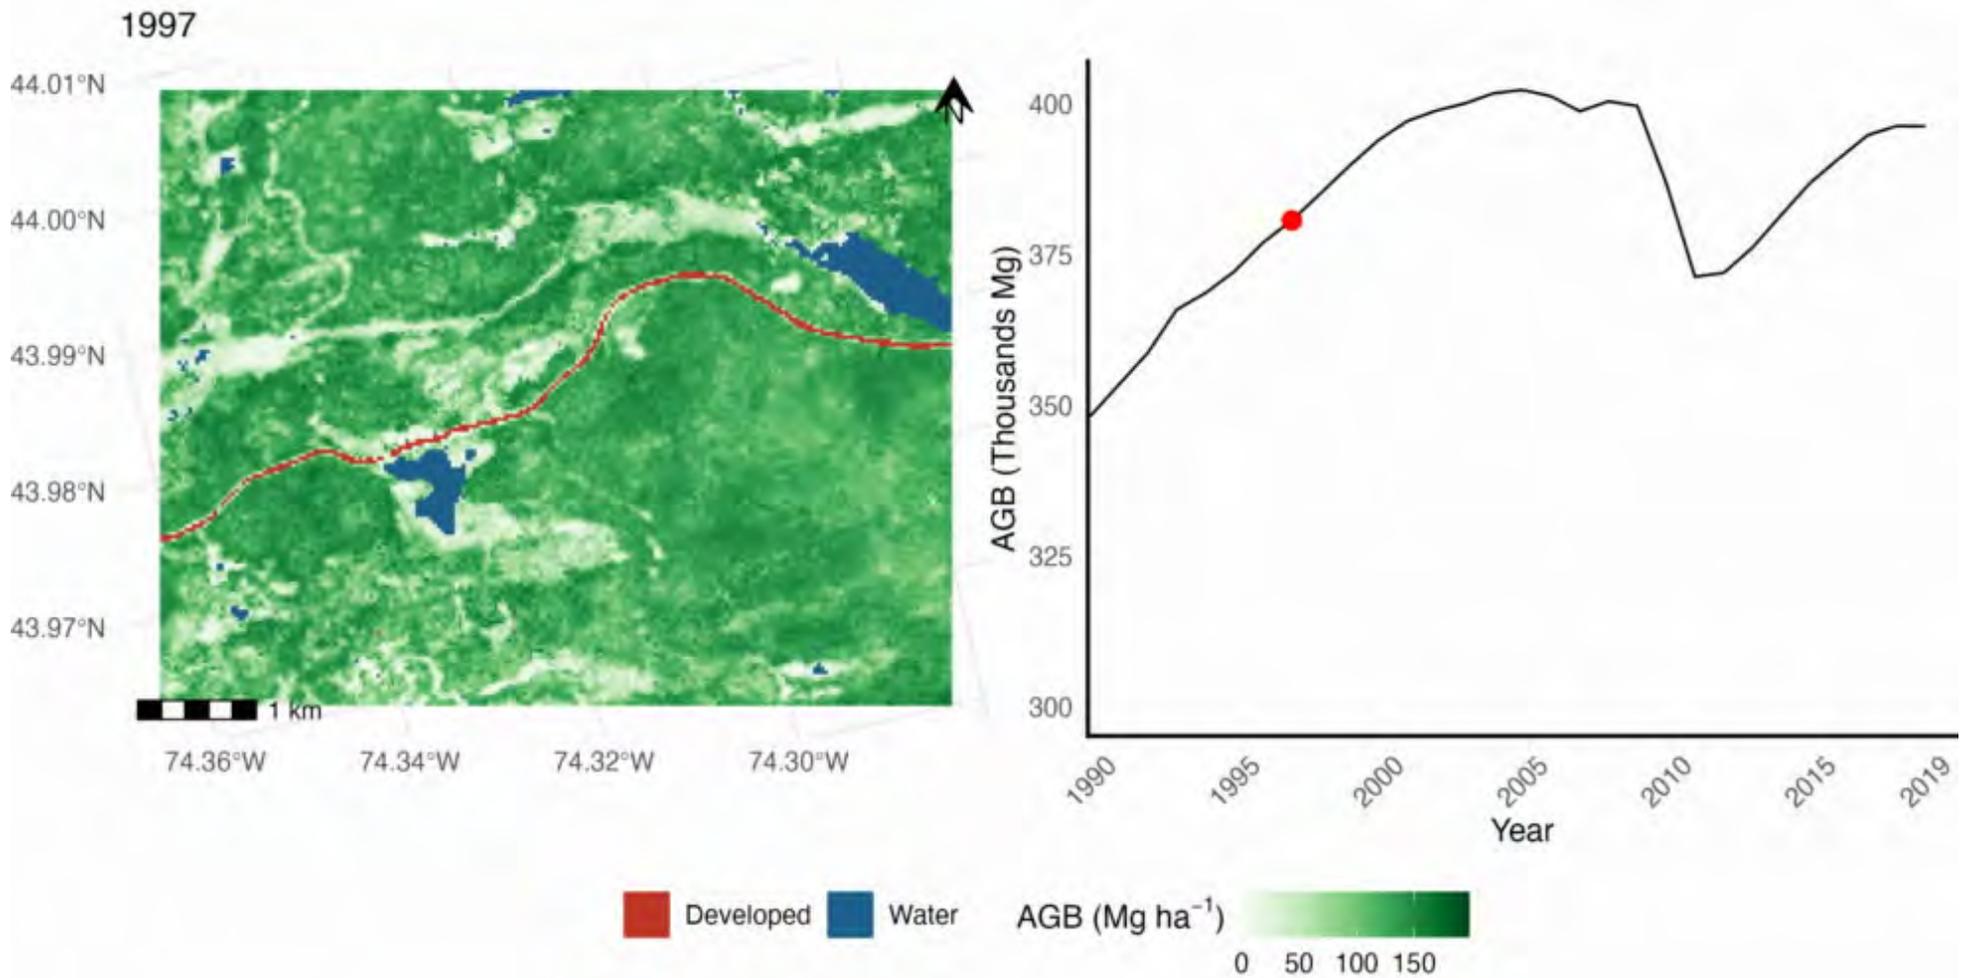

- simple differencing
- trend analysis
- temporal segmentation

# Stock-Change

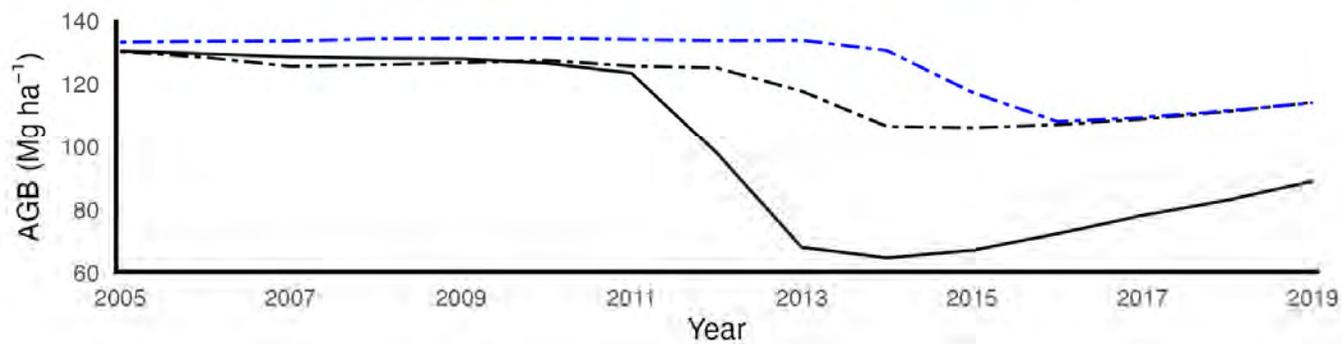

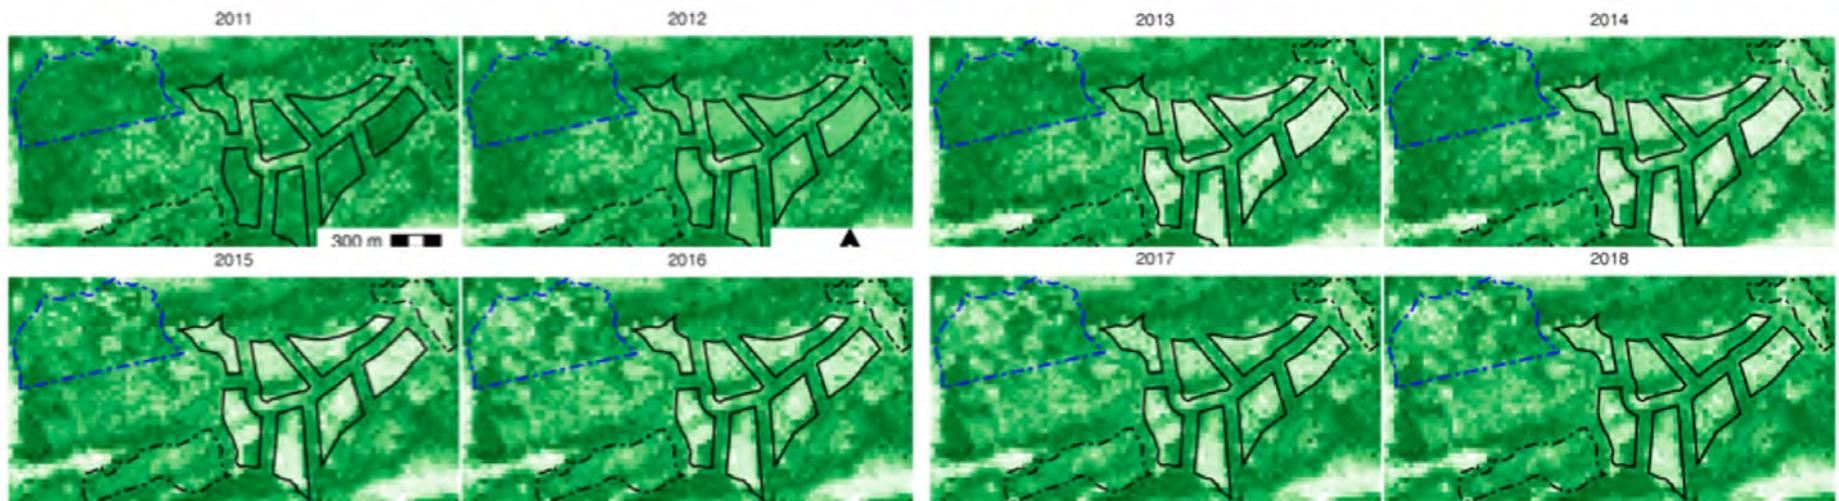

$\Delta$  Live C, 2019 - 1990 ( $\text{Mg ha}^{-1}$ )

## Monitoring

As Landsat imagery collections are updated annually with new imagery, we use our models to produce 'annual update' maps of AGB and C stocks. New maps are added to raster stacks and stock-change metrics are recalculated for ongoing monitoring.

## Monitoring

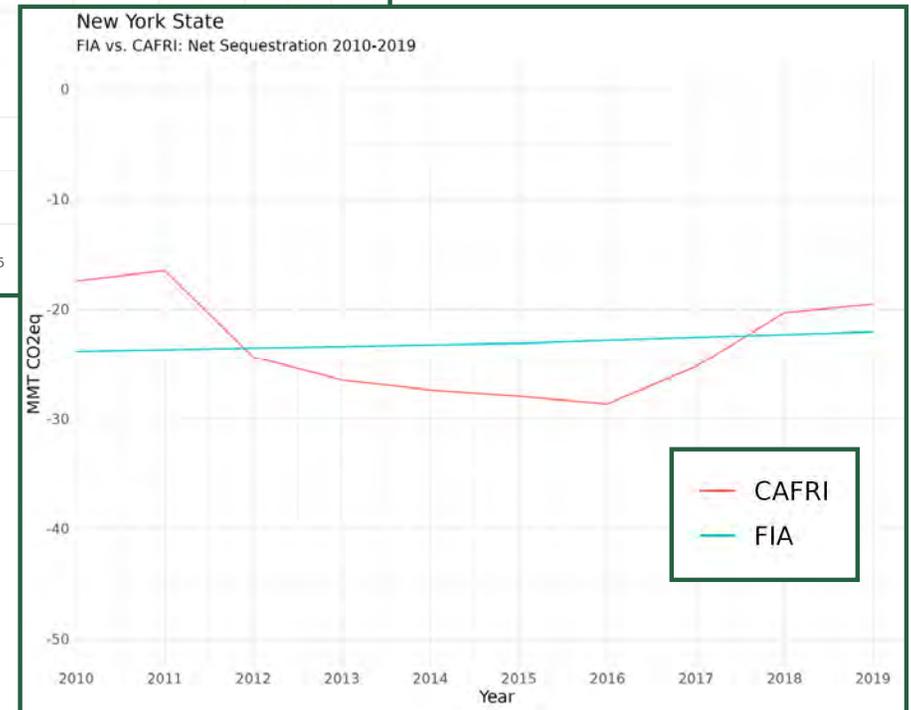

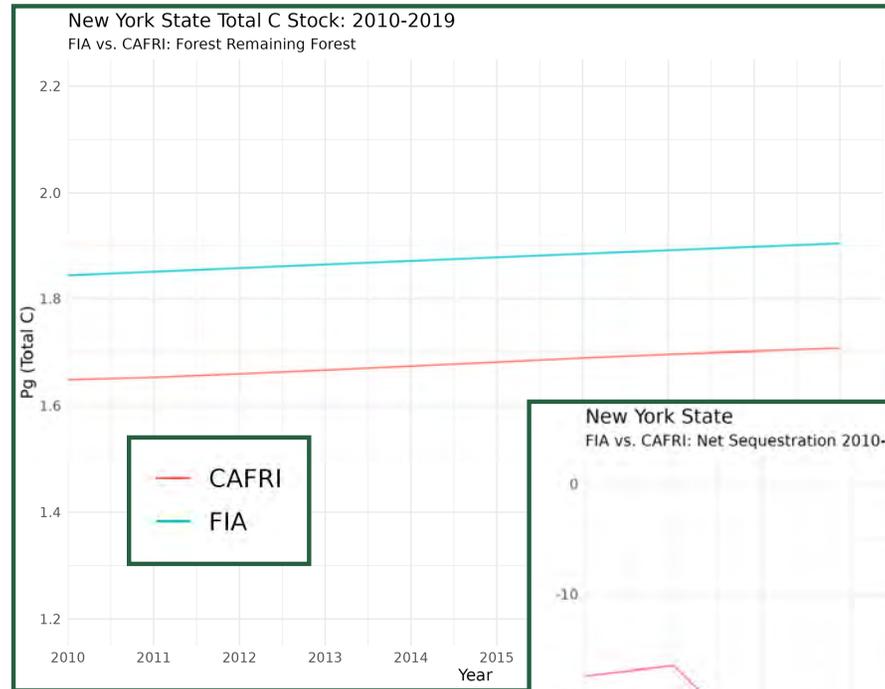

Map time-series accurately represent known patterns of disturbance, such as harvesting, in terms of timing, location, and relative magnitude (of volume removals). Modeled biomass recovery rates from 1-14 years post-harvest are faster than field-based estimates, but becomes consistent with field-derived growth curves at 15+ years after harvesting.

Carbon accounting workflow combines our C stock-change rasters, annual LULC products (LCMAP) and reference data for conversions (FIA, IPCC)

Replicates IPCC's AFOLU Tier-3 Stock-Change methodology used by EPA GHG Reporting Program

Highest confidence in live C accounting on forest lands remaining forest

Soil C spatially resolved, but can only change over time due to LULC conversions (forested land loss and gain)

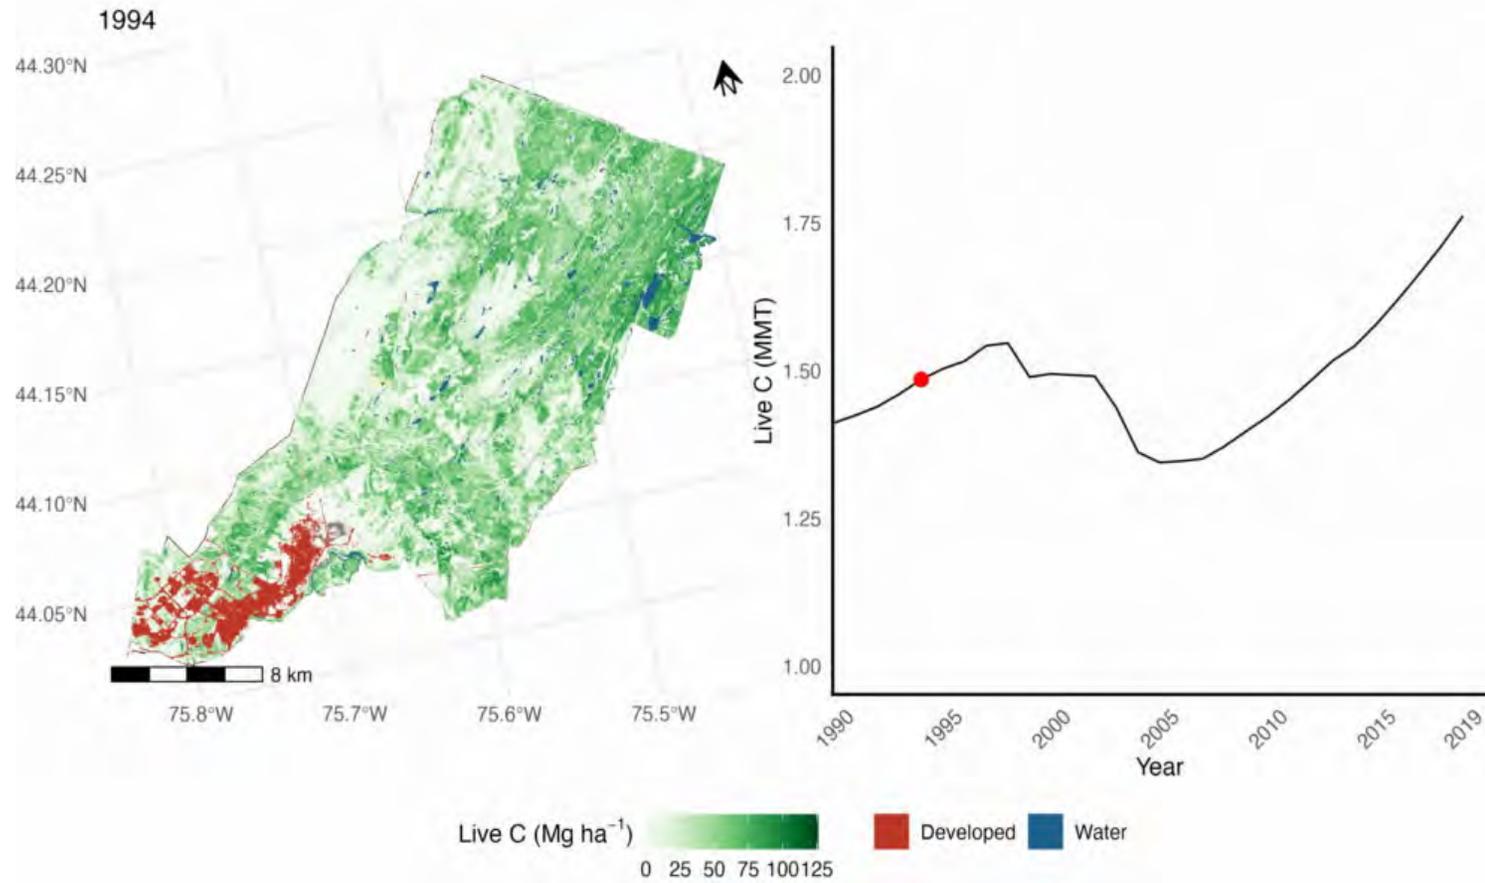

**GHG Inventory**

Carbon accounting workflow combines our C stock-change rasters, annual LULC products (LCMAP) and reference data for conversions (FIA, IPCC)

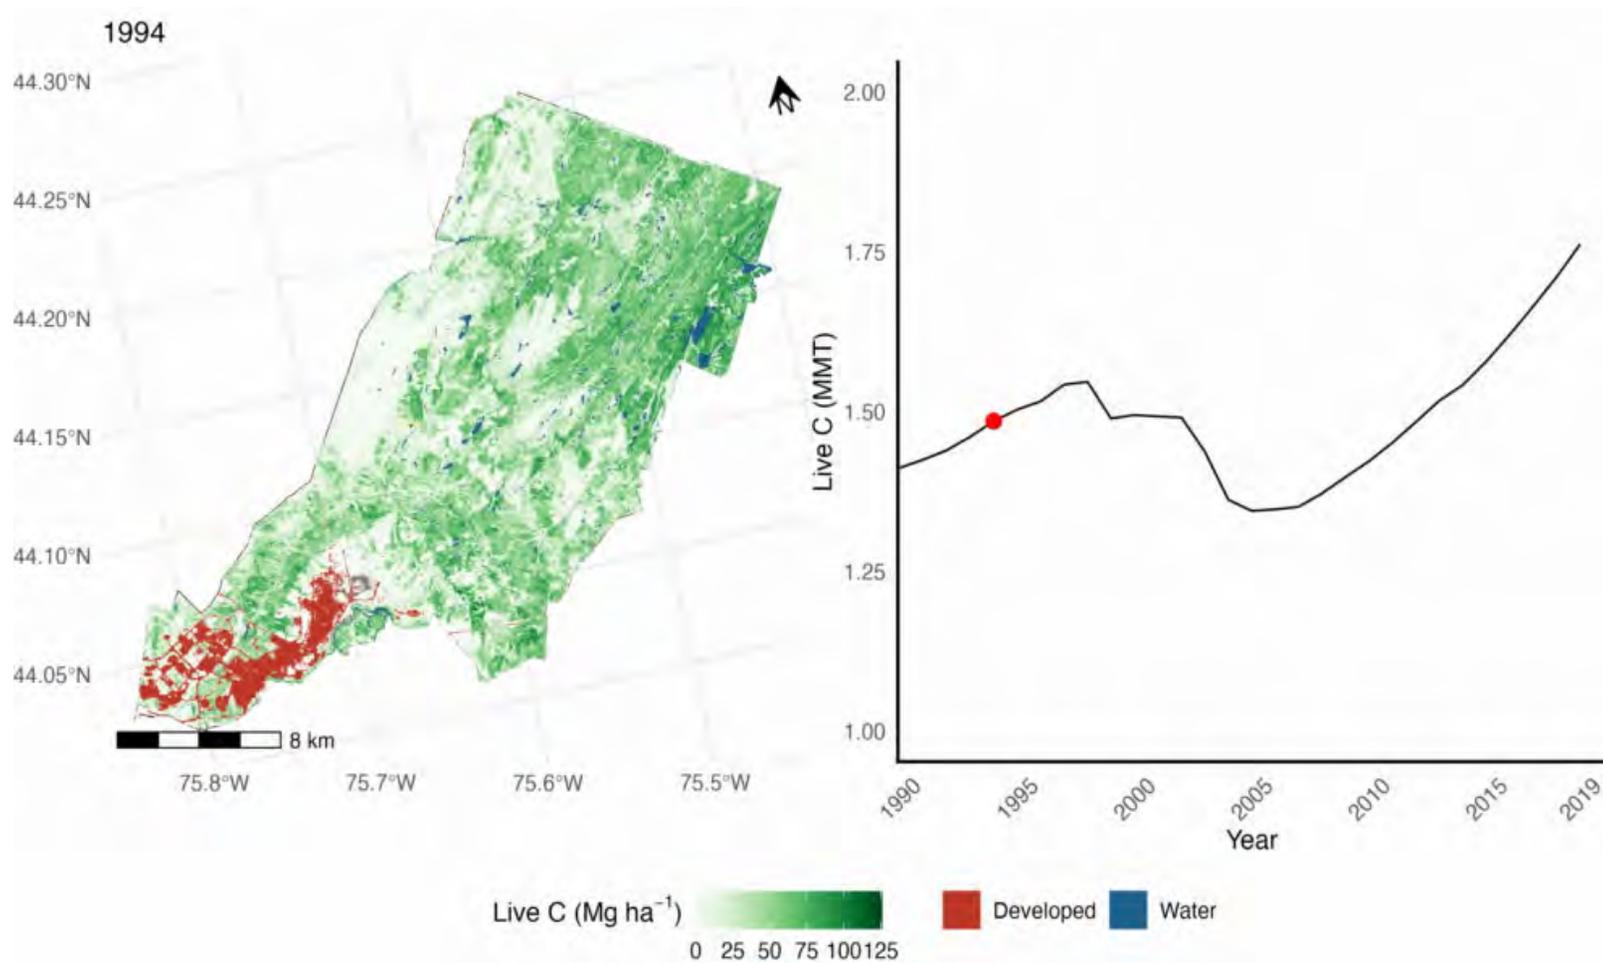

Replicates IPCC's AFOLU Tier-3 Stock-Change methodology used by EPA GHG Reporting Program

Highest confidence in live C accounting on forest lands remaining forest

Soil C spatially resolved, but can only change over time due to LULC conversions (forested land loss and gain)

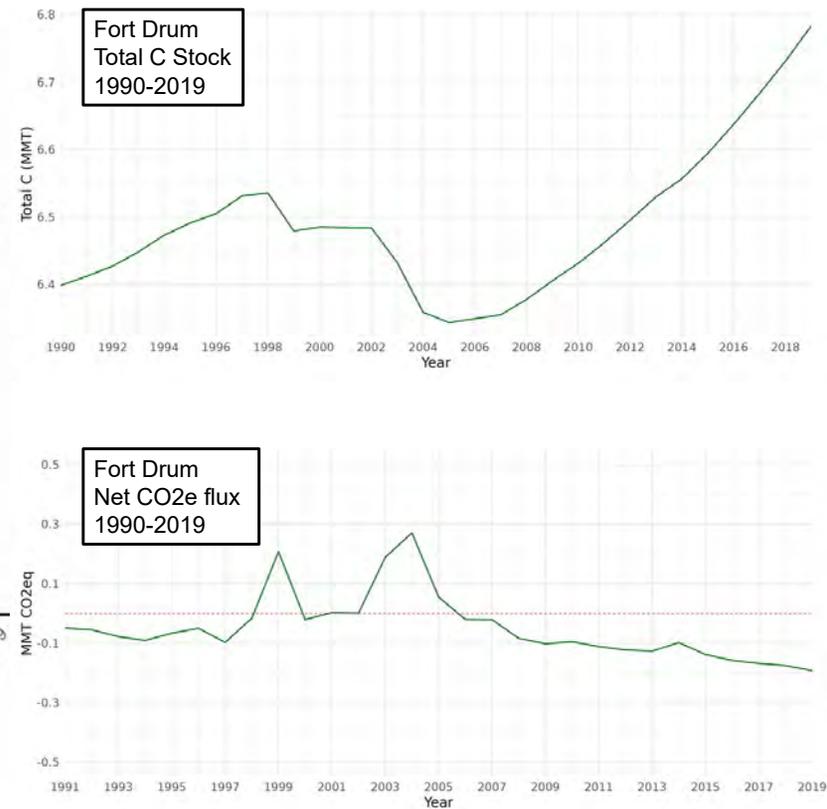

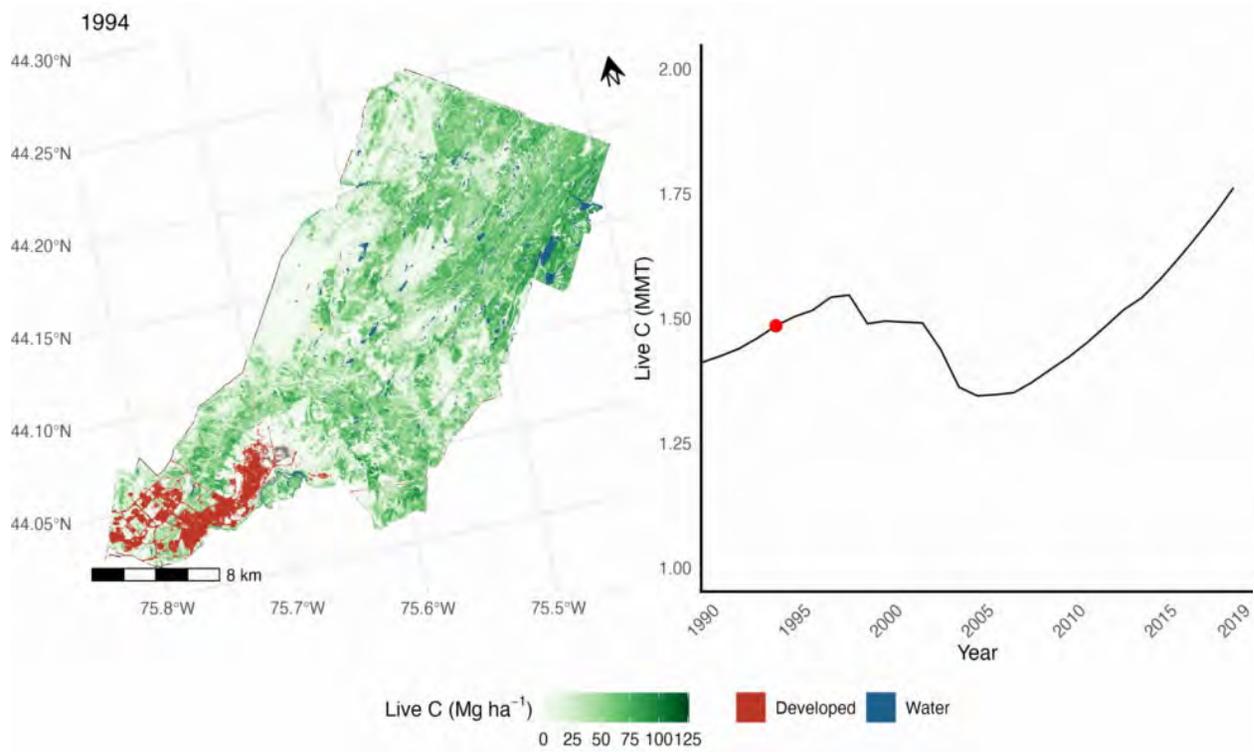

**GHG Inventory**

## GHG Inventory

Carbon accounting workflow combines our C stock-change rasters, annual LULC products (LCMAP) and stock-change reference data (FIA, IPCC)

Replicates IPCC's AFOLU Tier-3 Stock-Change methodology used by EPA GHGRP

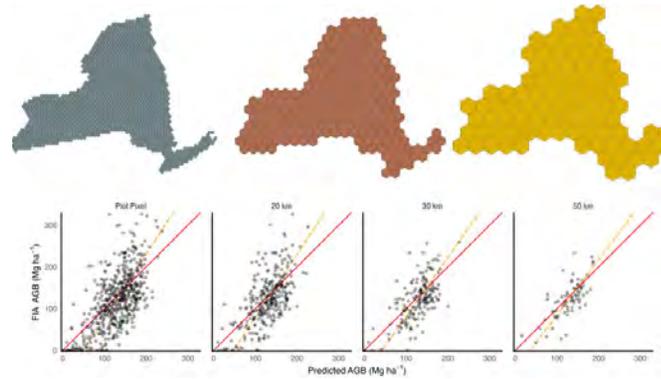

## GHG Inventory

Carbon accounting workflow combines our C stock-change rasters, annual LULC products (LCMAP) and stock-change reference data (FIA, IPCC)

Replicates IPCC's AFOLU Tier-3 Stock-Change methodology used by EPA GHGRP

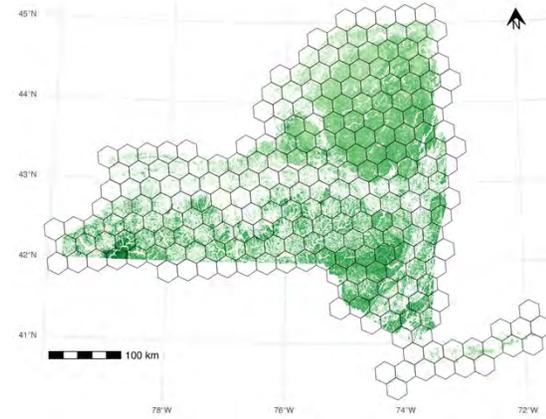

## Model

Prediction accuracy on 70/30 training holdout plots; k-fold cross-validation, hyperparameter tuning; ensembling

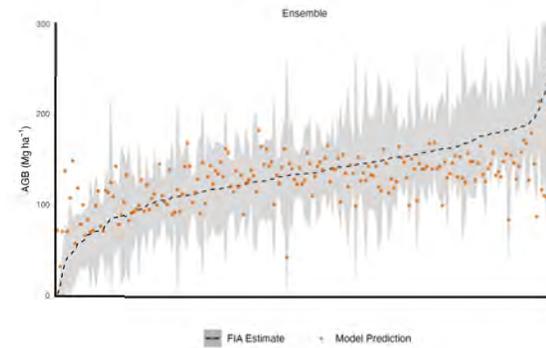

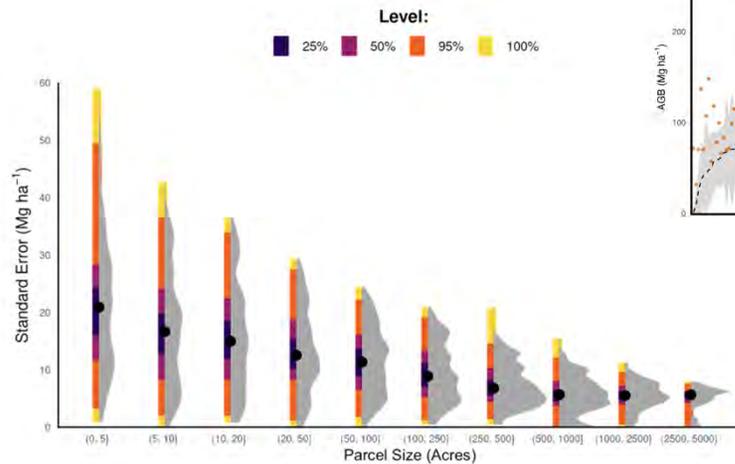

## Map

Plot-to-pixel comparisons aggregated to variable scales (Riemann et al. 2010); LULC-corrected validation vs FIA small-area hexagons (Menlove & Healey 2021)

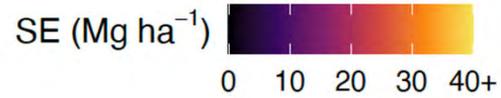

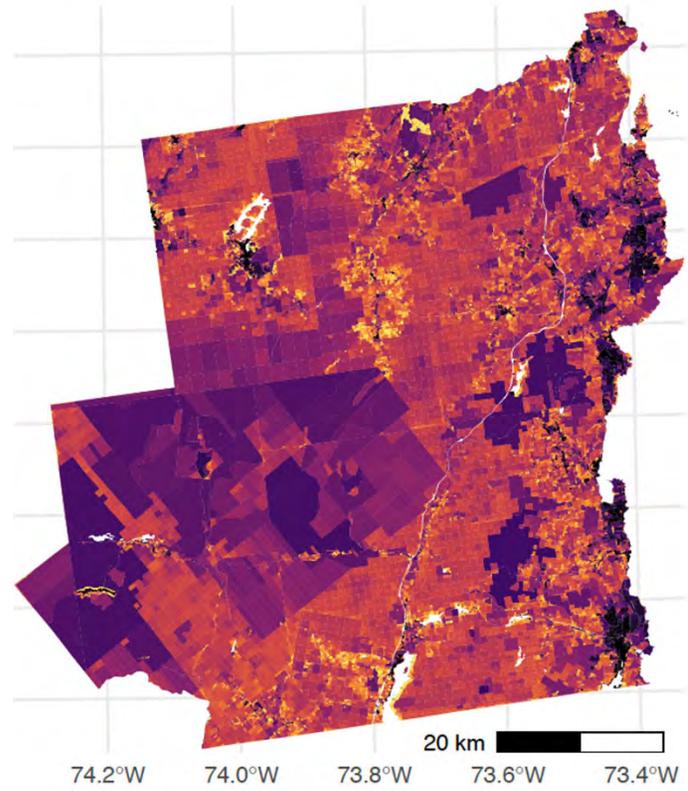

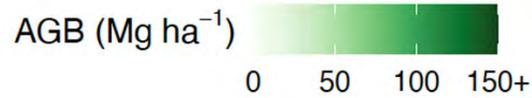

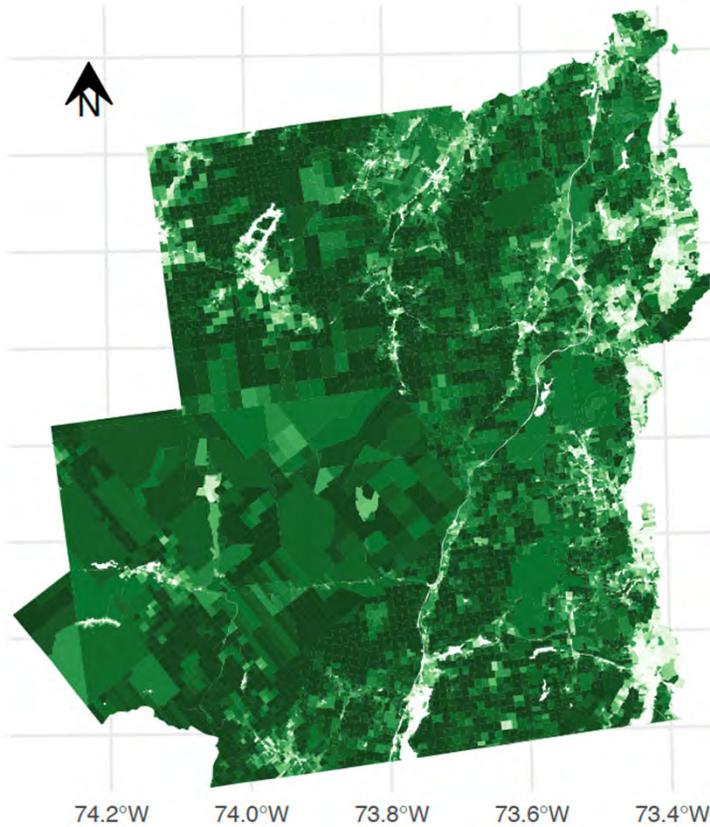

## Scale

Bootstrapped cumulative uncertainty from reference plots, model residuals, spatial autocorrelation, etc. provides estimate of standard error per parcel

## Uncertainty

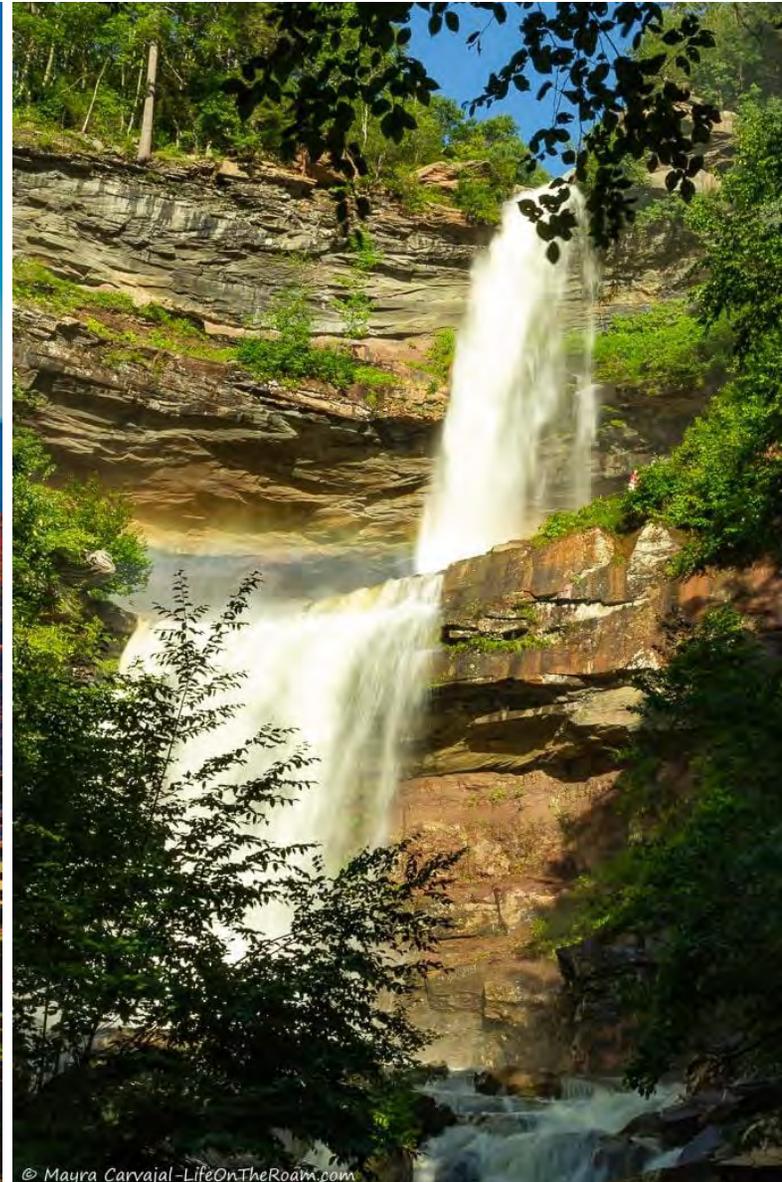

## Uncertainty

Continuous maps summarized by parcel boundaries = property-level estimates  
Map uncertainty is related to parcel size, shape, prediction range, % forest, etc  
Can now estimate parcel-level standard error of map data (Johnson et al. 2025 RSE)

Biomass, live carbon (C) stocks  
have grown regionally since 1990

# C Stocks & Changes

Biomass, live carbon (C) stocks have grown regionally since 1990

Land use and topography drive patterns in live C density and net gains/losses in live C stocks

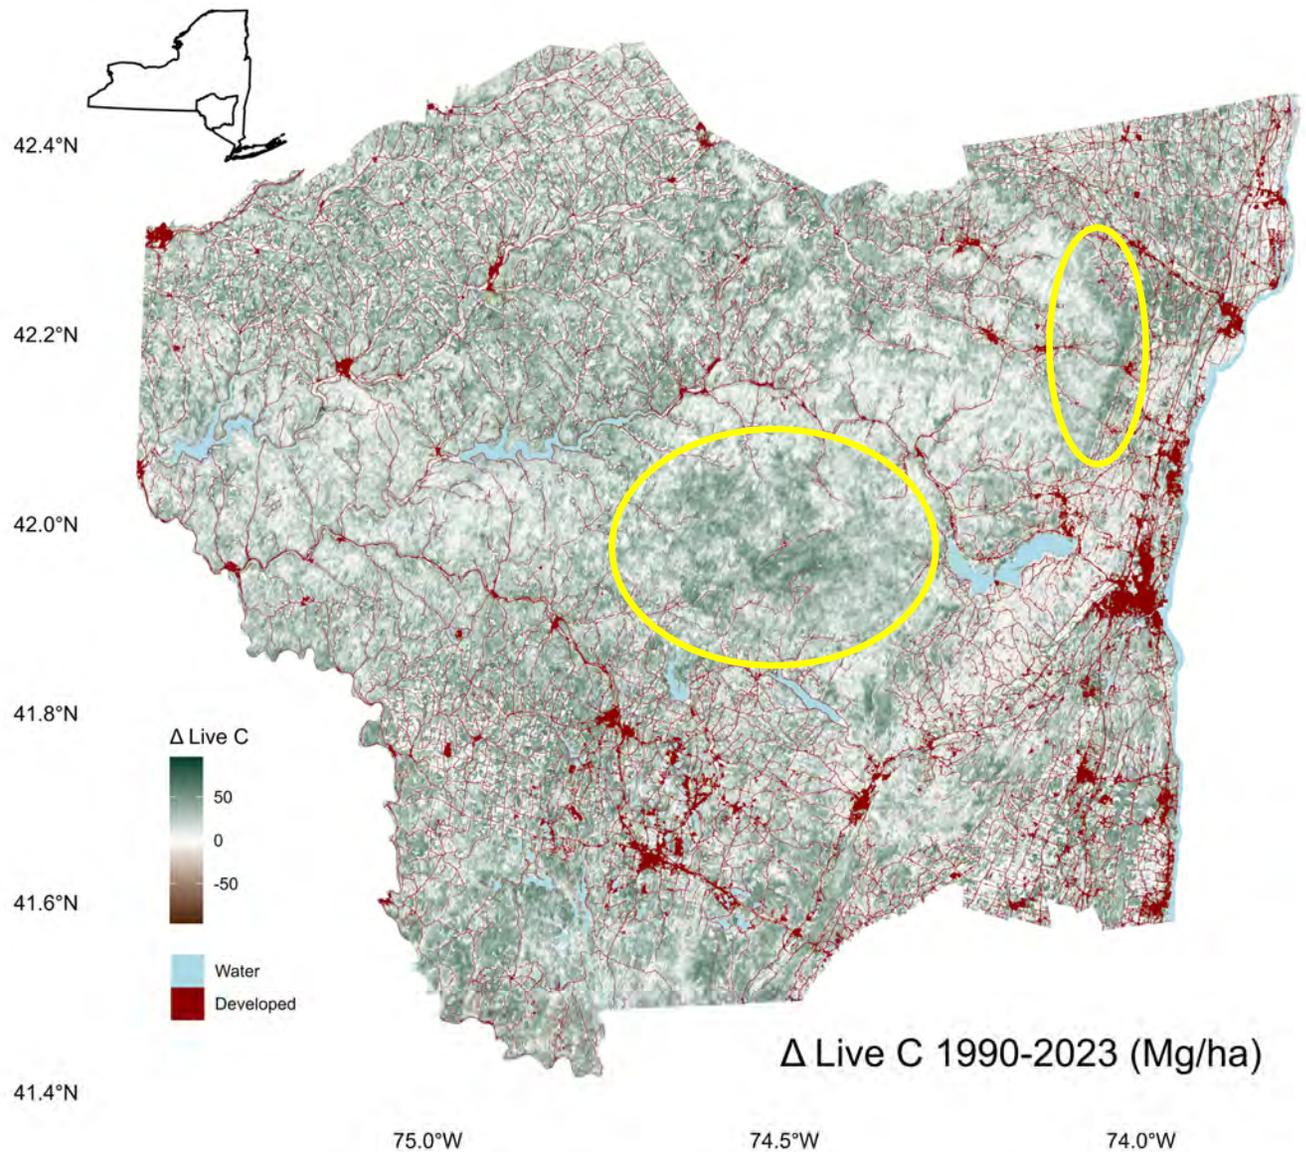

## C Stocks & Changes

Biomass, live carbon (C) stocks have grown regionally since 1990

Land use and topography drive patterns in live C density and net gains/losses in live C stocks

Regional carbon sink includes contiguous tracts within reserves (southcentral, northeast C. Park)

## C Stocks & Changes

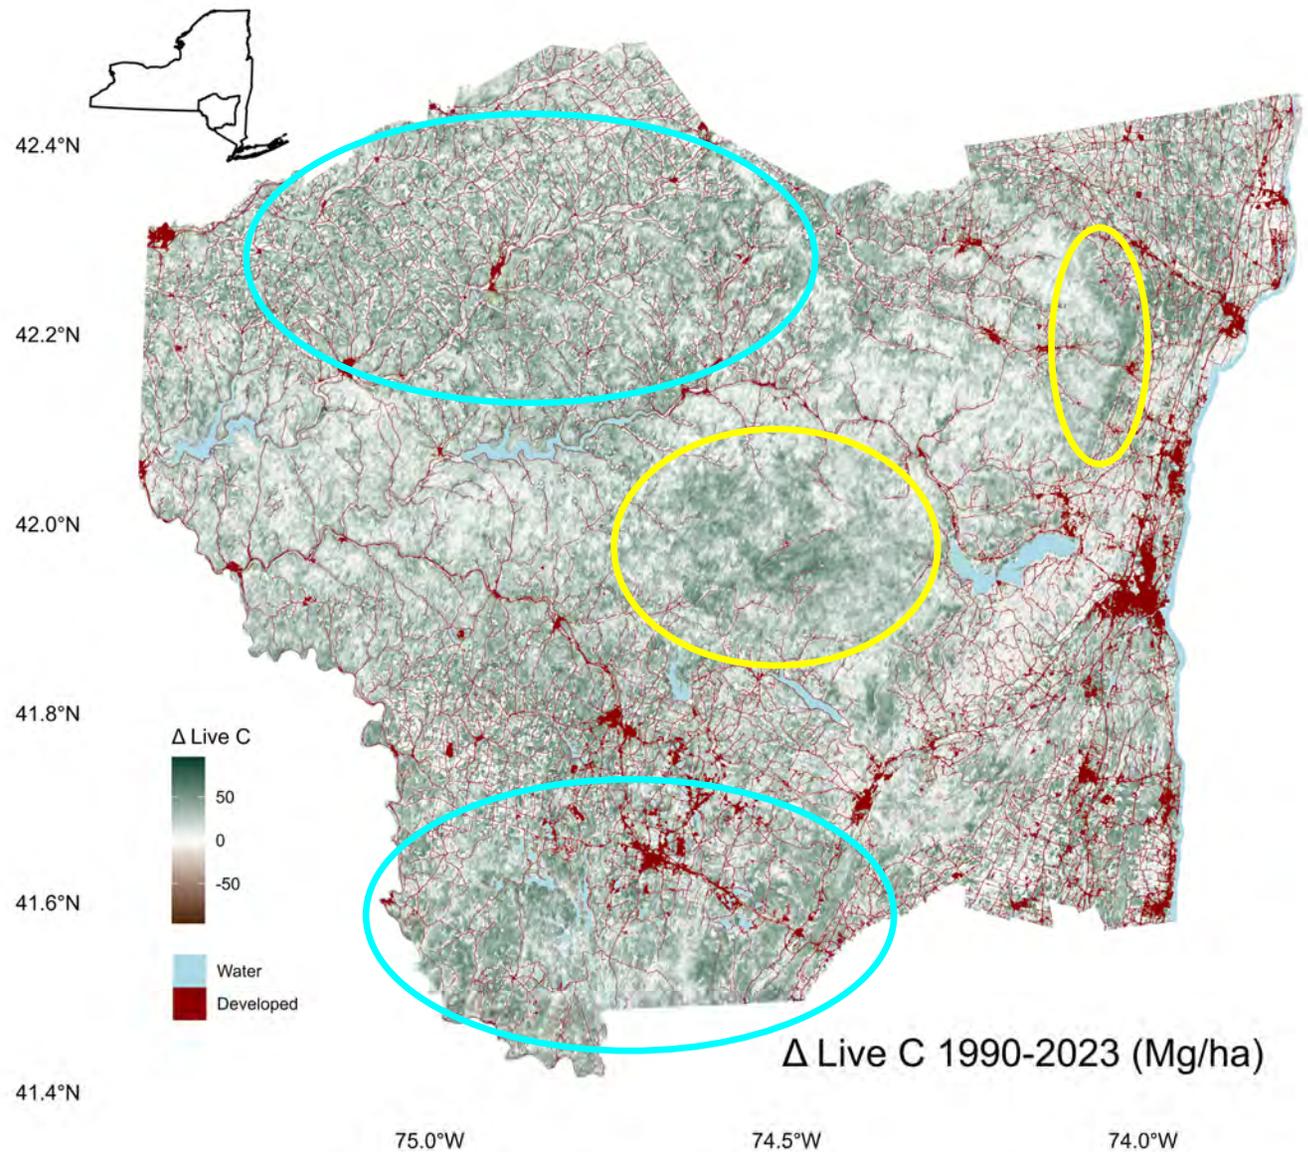

Biomass, live carbon (C) stocks have grown regionally since 1990

Land use and topography drive patterns in live C density and net gains/losses in live C stocks

Regional carbon sink includes contiguous tracts within reserves (southcentral, northeast C. Park)

...and many smaller fragmented patches in more developed areas (Delaware, Sullivan Co.)

## C Stocks & Changes

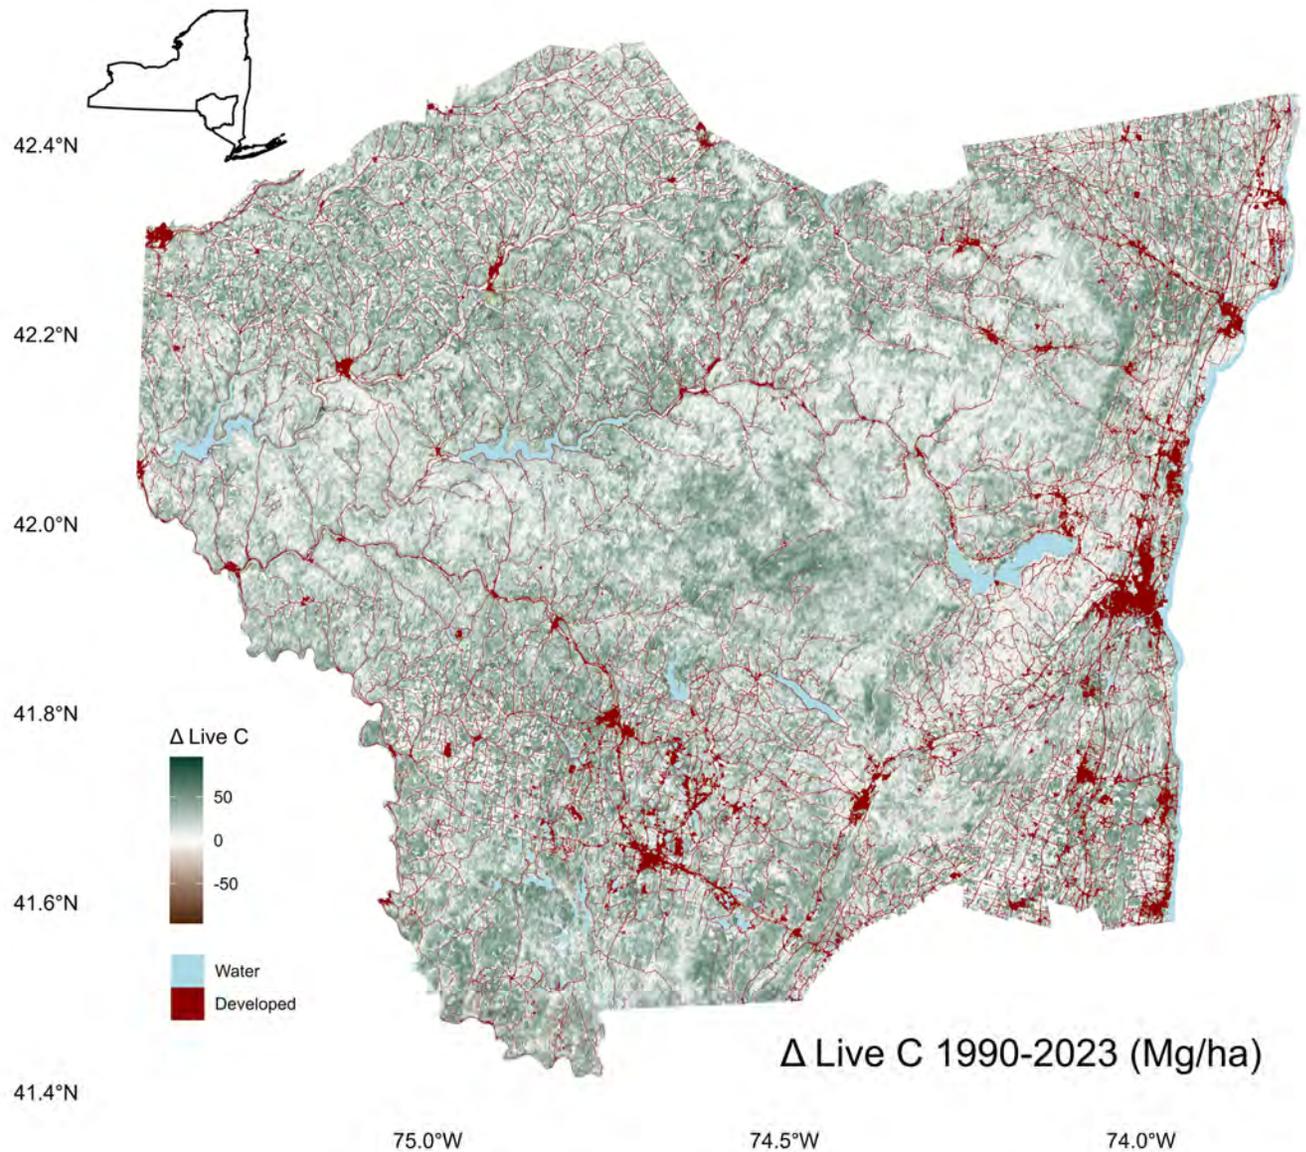

Biomass, live carbon (C) stocks have grown regionally since 1990

Land use and topography drive patterns in live C density and net gains/losses in live C stocks

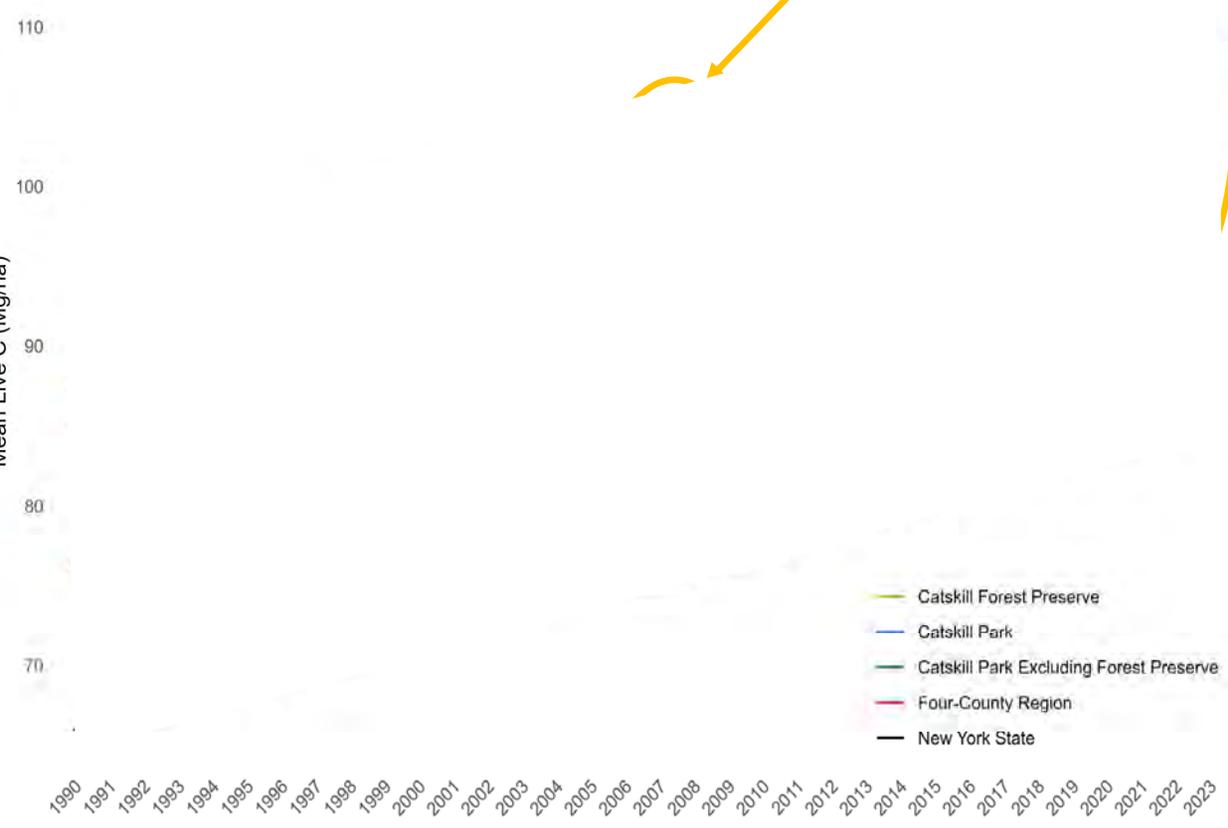

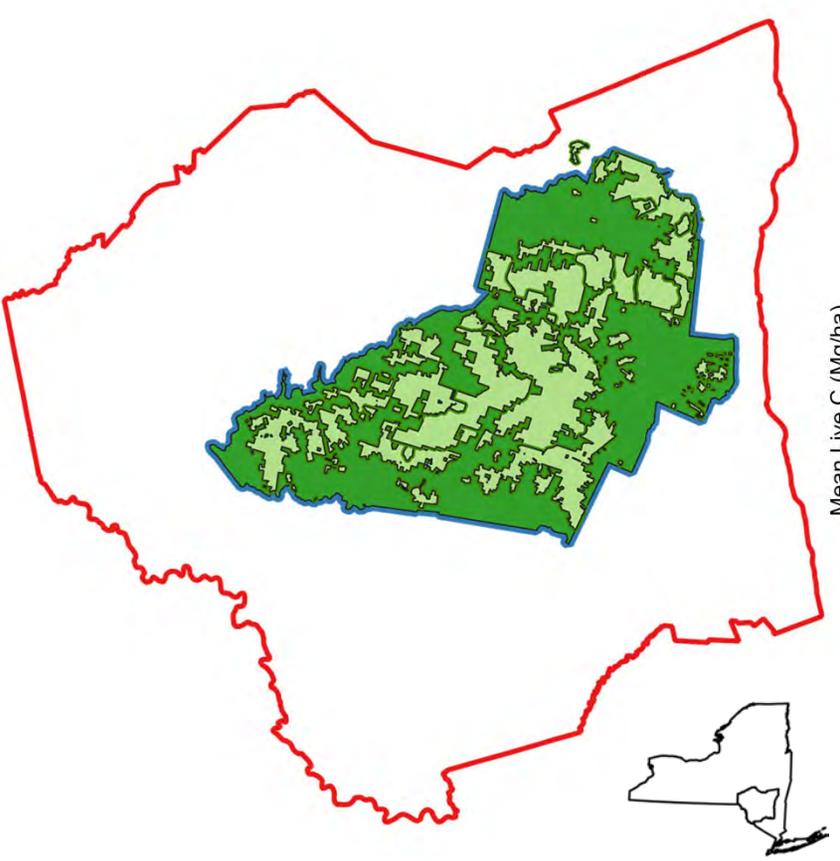

Regional carbon sink includes contiguous tracts within reserves (southcentral, northeast C. Park)

...and many smaller fragmented patches in more developed areas (Delaware, Sullivan Co.)

Most forest conversion due to development in peri-urban areas

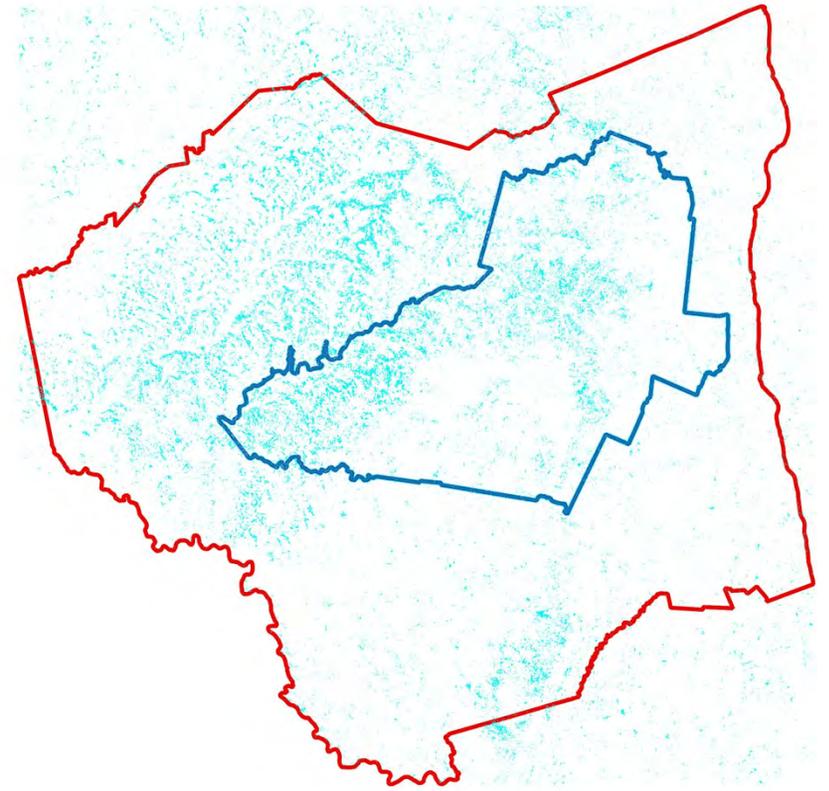

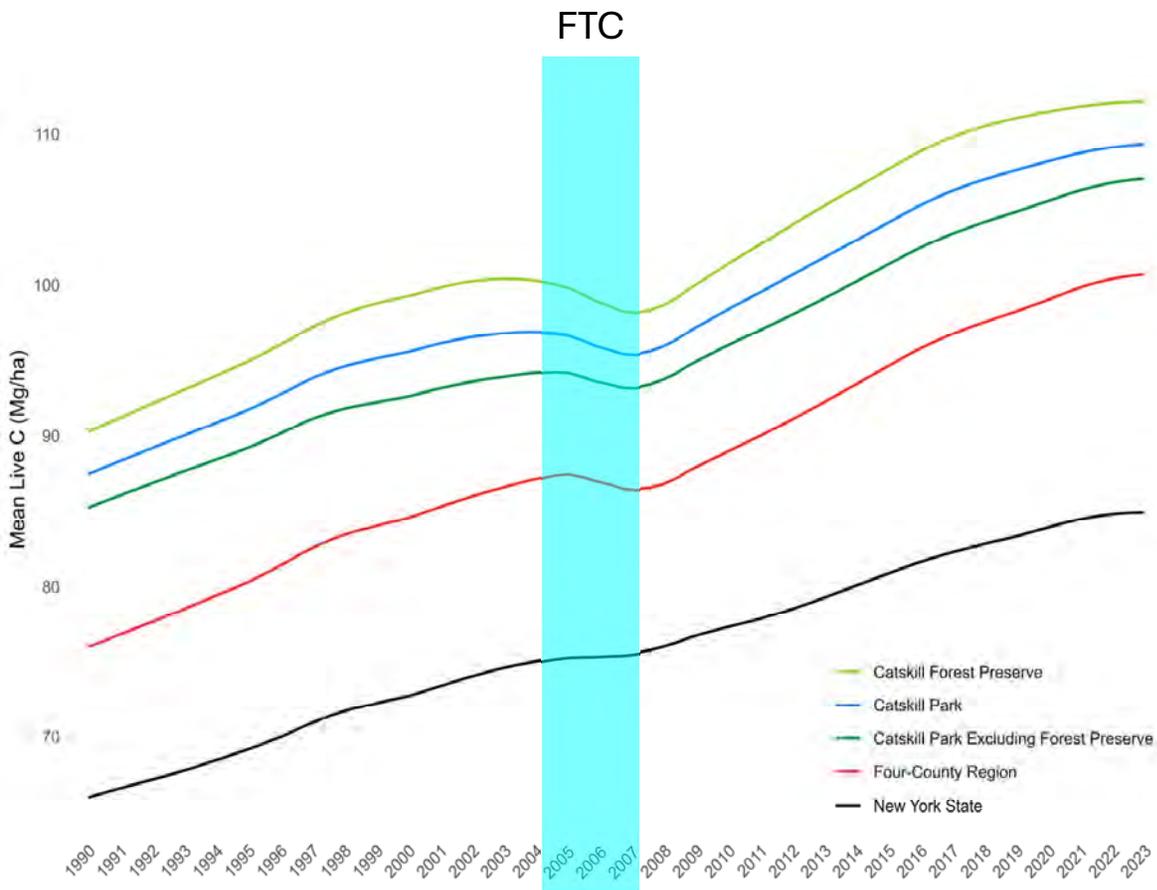

## C Stocks & Changes

## Insights

- Catskills Park and Forest Preserve have higher average live C density than rest of region and state
- Similar patterns of live C stock-change over 30+ years = similar rates of C sequestration
- Within region, live C max ~170 Mg/ha, suggesting ample 'room' for future growth (and C seq)

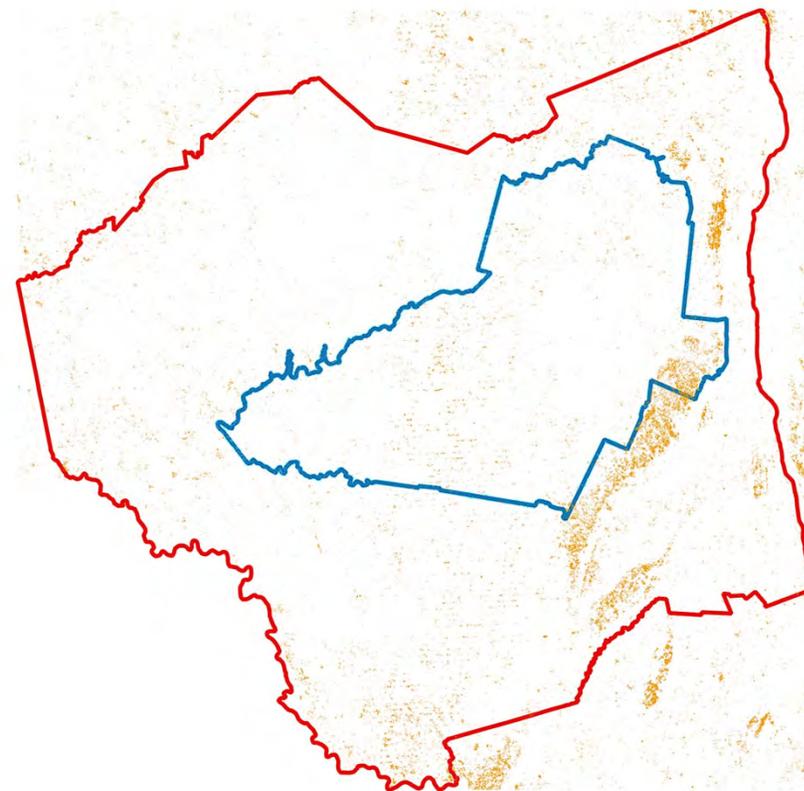

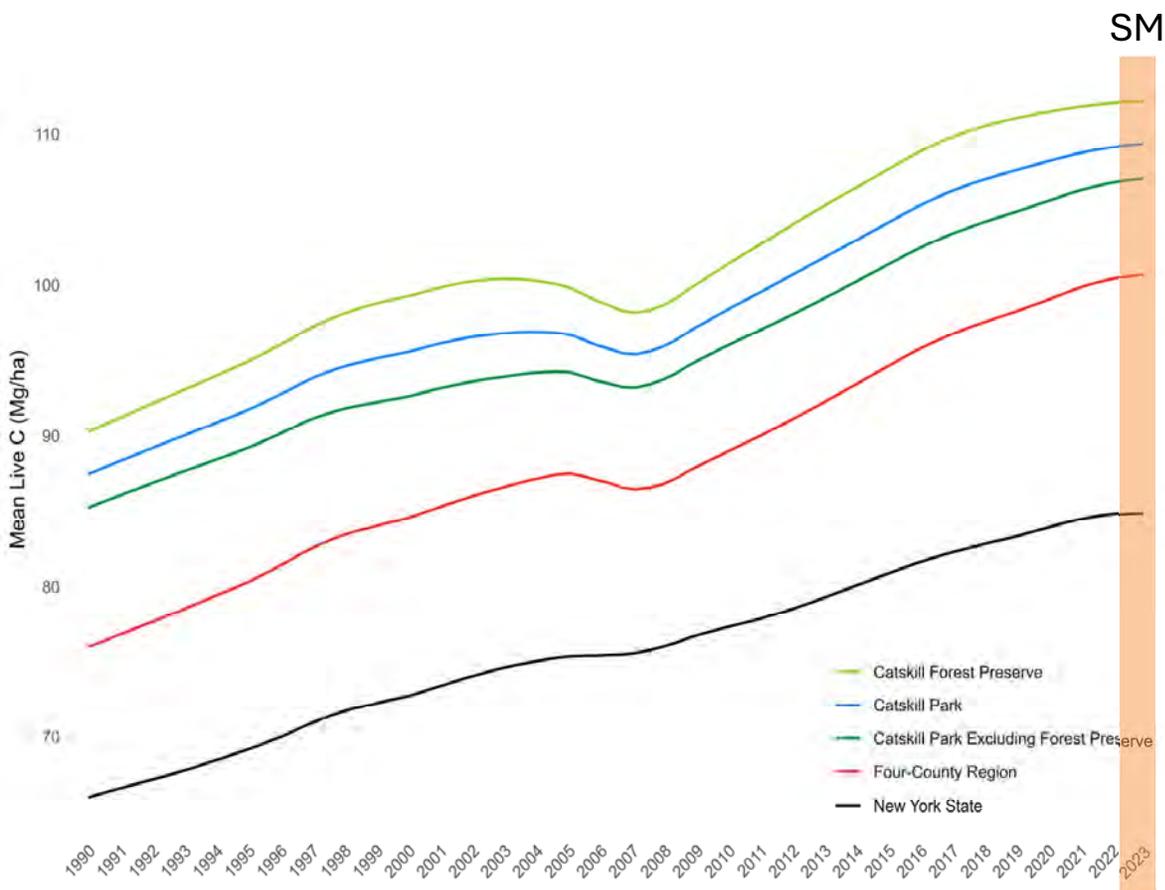

## Insights

**2005-2007:** outbreaks of forest tent caterpillar (FTC; *Malacosoma disstria*) across NYS and broader region. Catskills were extensively impacted, especially in the cooler N-facing and mid-elevation habitats where northern hardwoods (maple-beech-birch) are common.

*Malacosoma disstria*

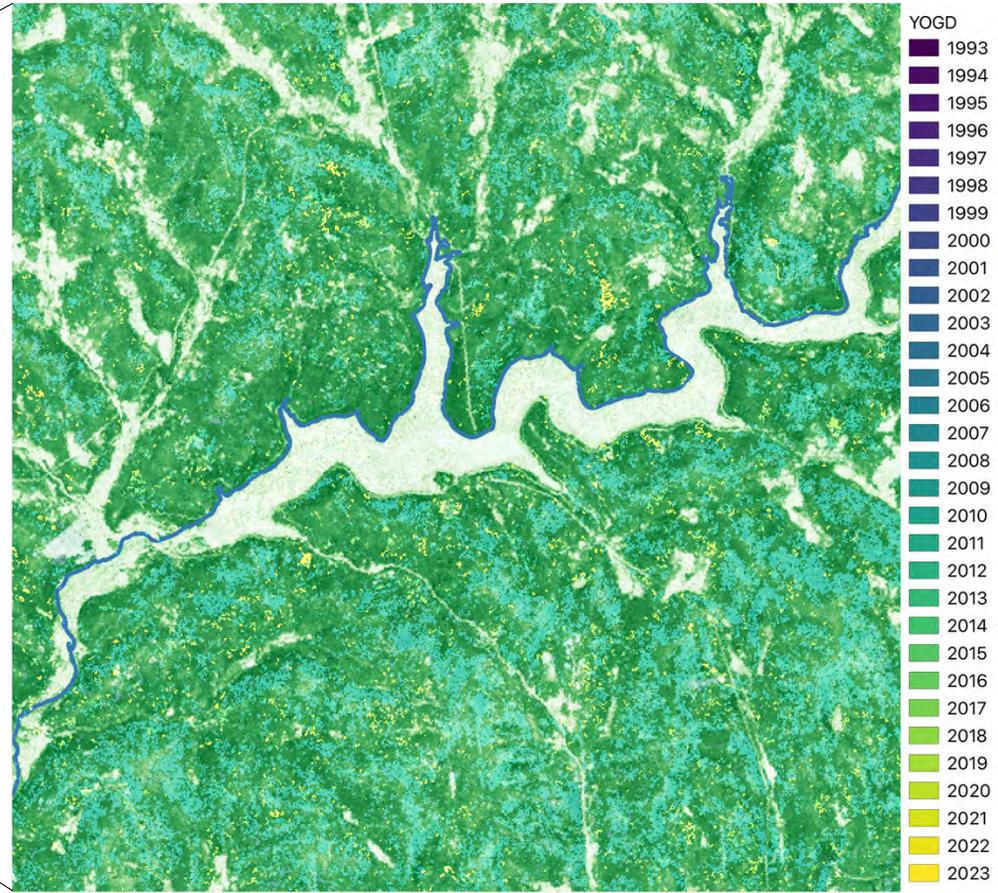

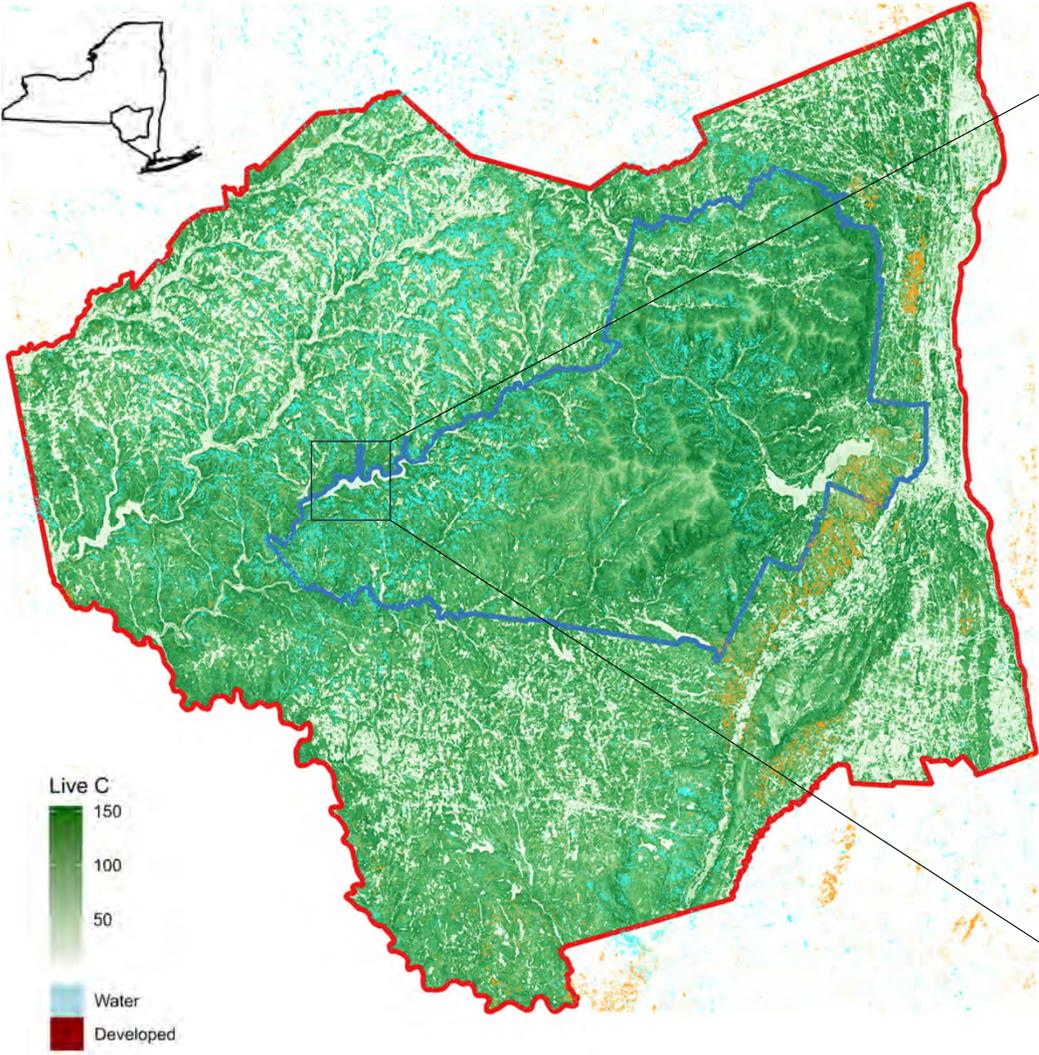

## Insights

**2023:** outbreaks of spongy moth (SM, *Lymantria dispar*) reported across lower Hudson Valley and Catskills. Areas of heavy defoliation were mainly located on warmer, S-facing slopes, escarpments, and valleys consistent with oak-hickory and mixed hardwood forests.

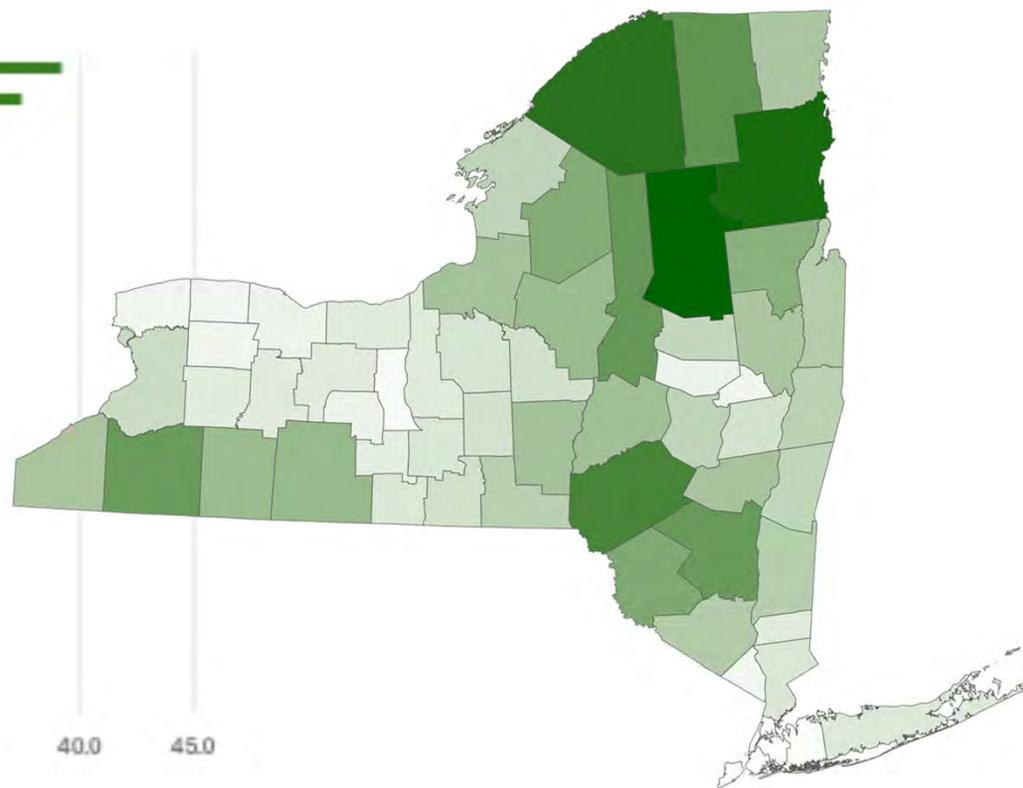

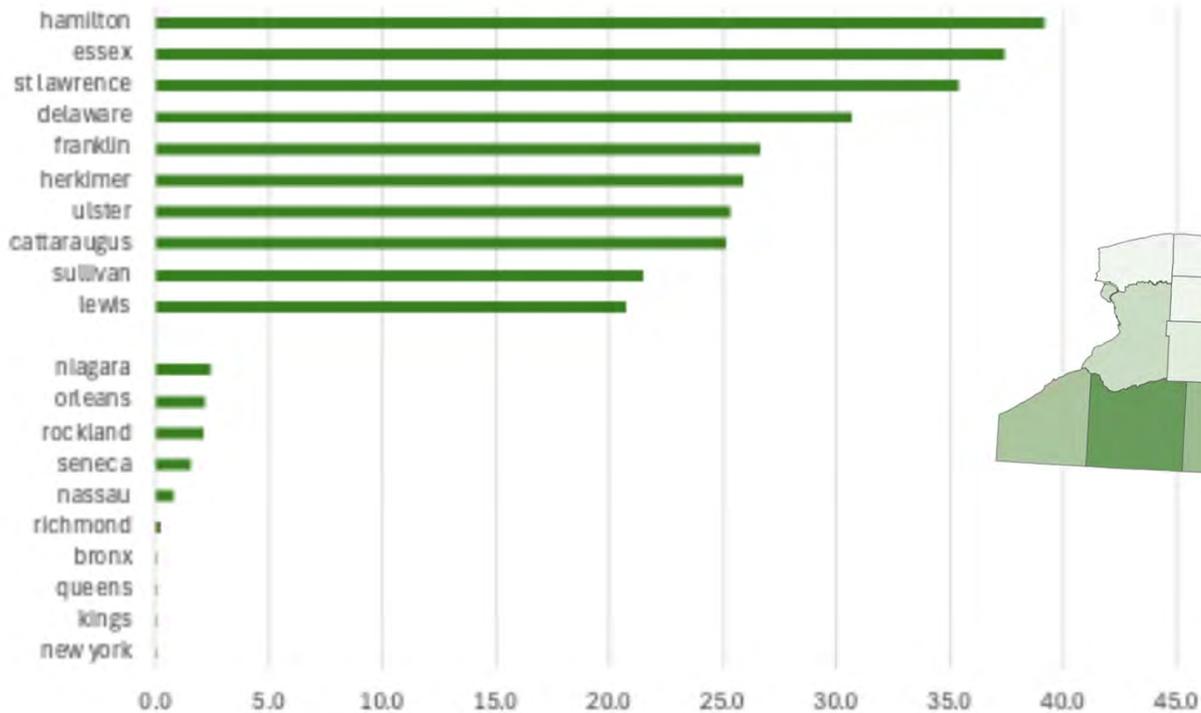

*Lymantria dispar*

**Role of Catskills  
in NYS Carbon Sink**

Continuous high-res maps can be summarized by geographic areas into discrete estimates

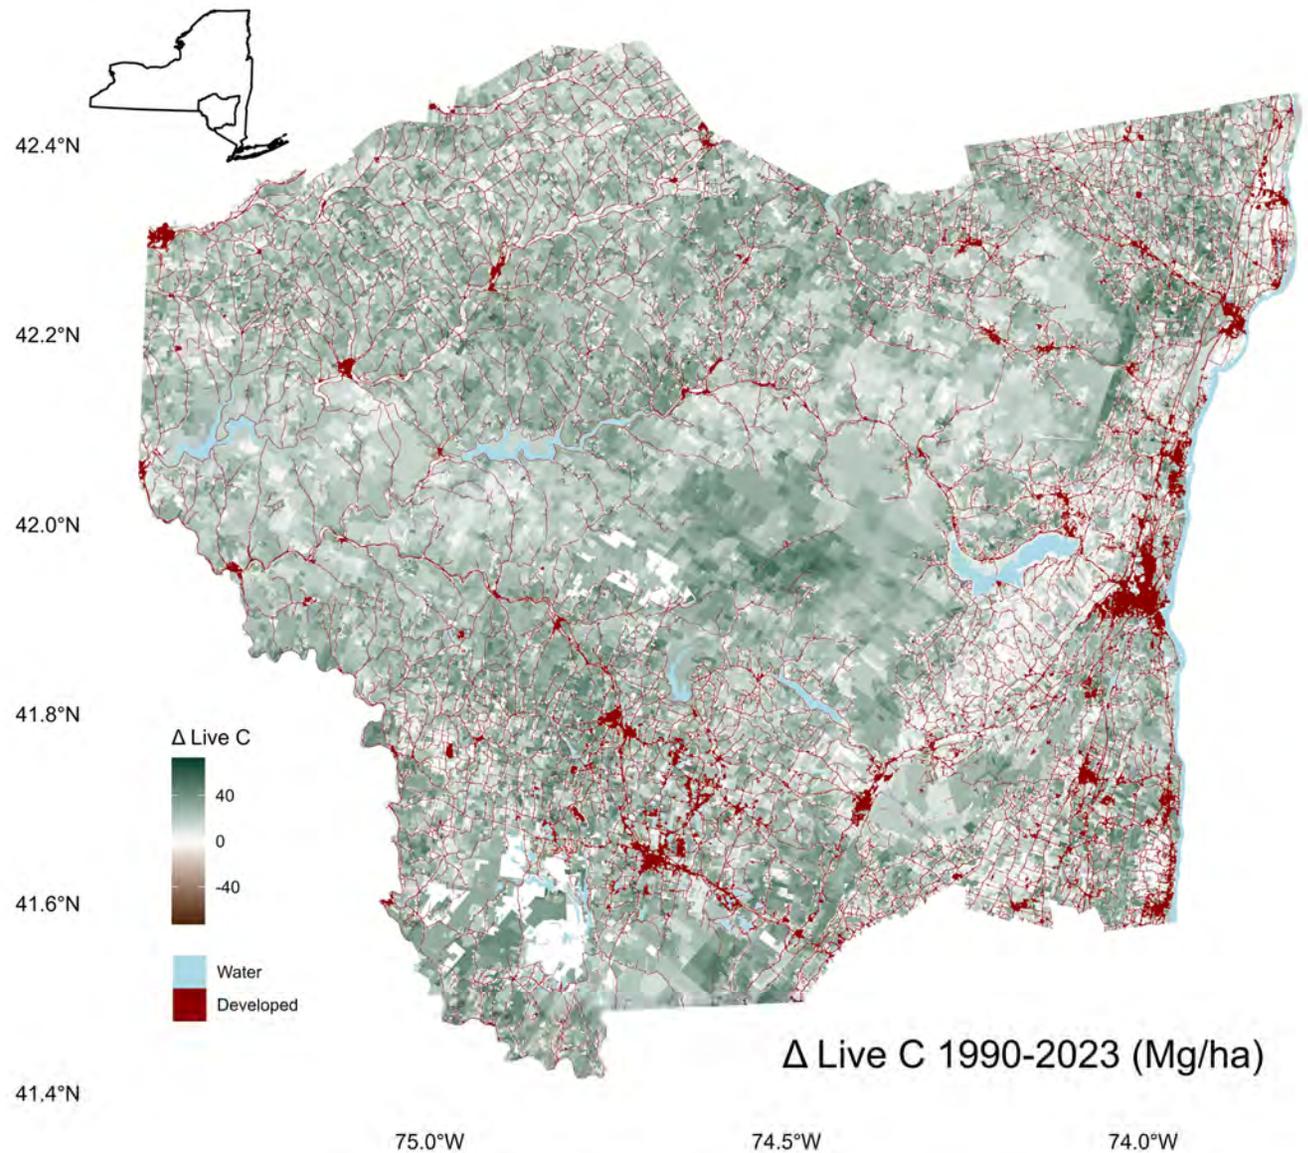

On public lands: management units and other designations

On private lands: parcels represent scale at which landowners make decisions

Parcel boundaries can be useful for understanding spatial patterns related to historical land use

Parcel boundaries subject to change (subdivision) over time, can be updated annually

## Insights

Most parcels in Catskills Park rank in top 20% for live C density statewide

Relatively few of these 'high C stock' parcels also rank top 20% statewide for live C seq (during 1990-2023)

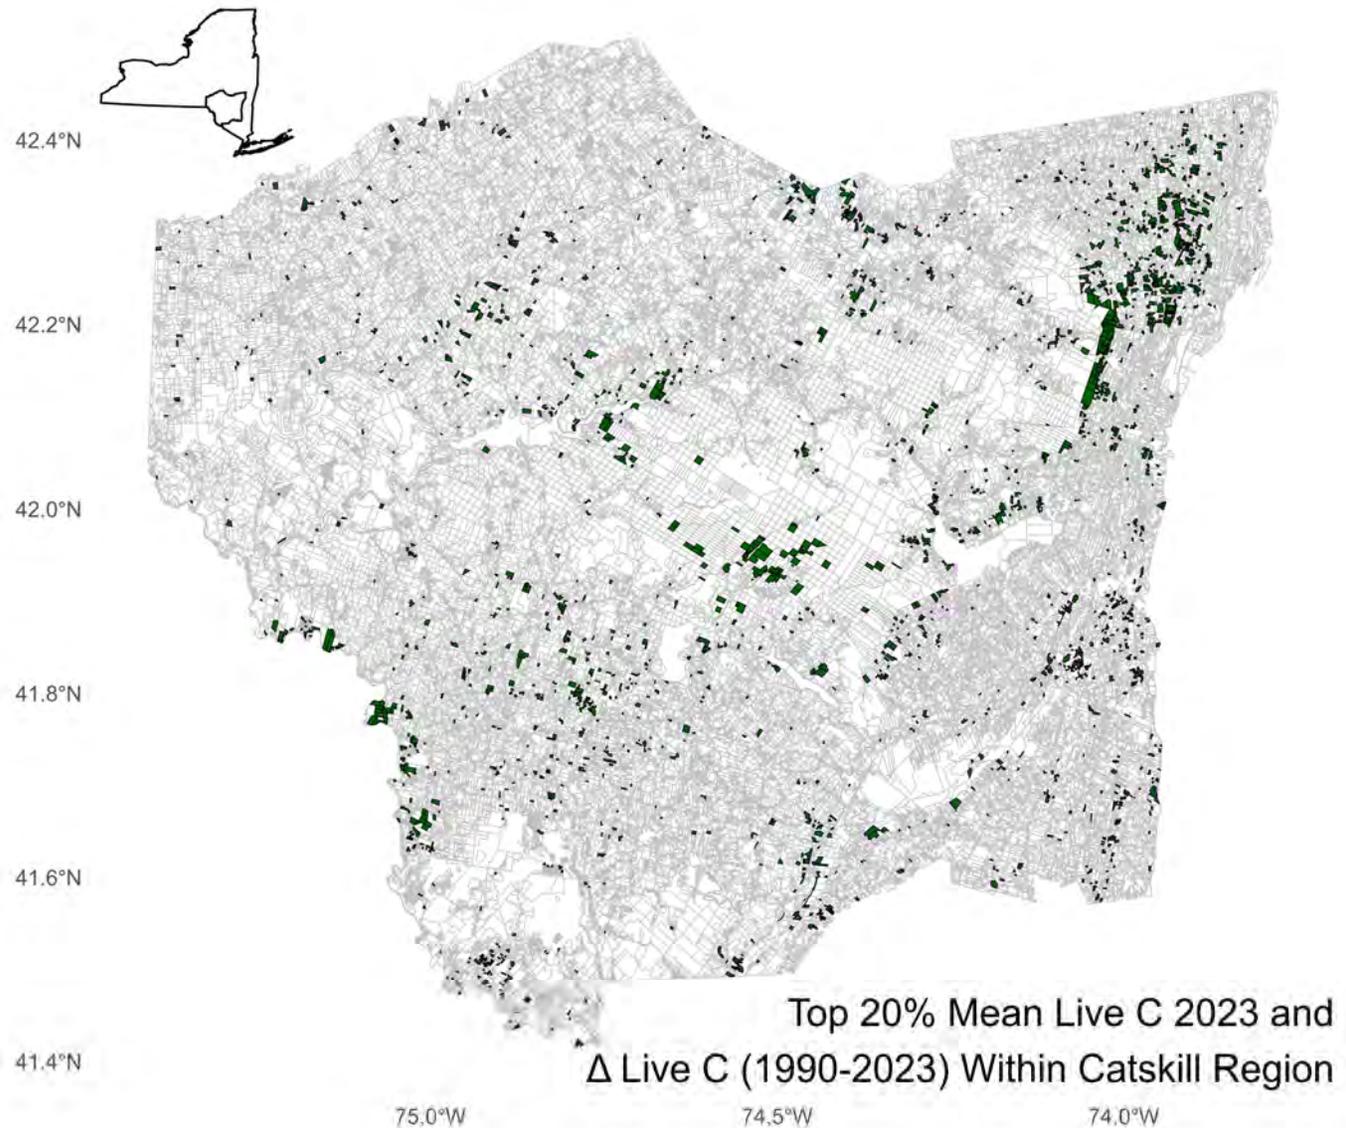

Catskills Park represents about 1/4<sup>th</sup> of the regional C sink...

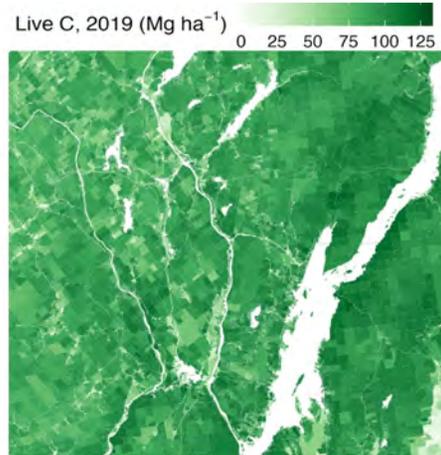

...its older forests may have slower C seq rates than younger regenerating forests outside of the Park...

...or our models are not fully capturing growth in older forests.

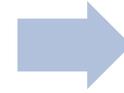

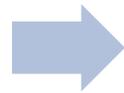

Parcels high in both C stocks and C seq rates = maximum climate ROI

**'Top Tier' Parcels**

Parcel-level carbon stocks

### Carbon stock density

Estimates CO<sub>2</sub> emissions that would occur due to forest land conversion

### Development Pressure

Forecast maps of future land use change under different scenarios

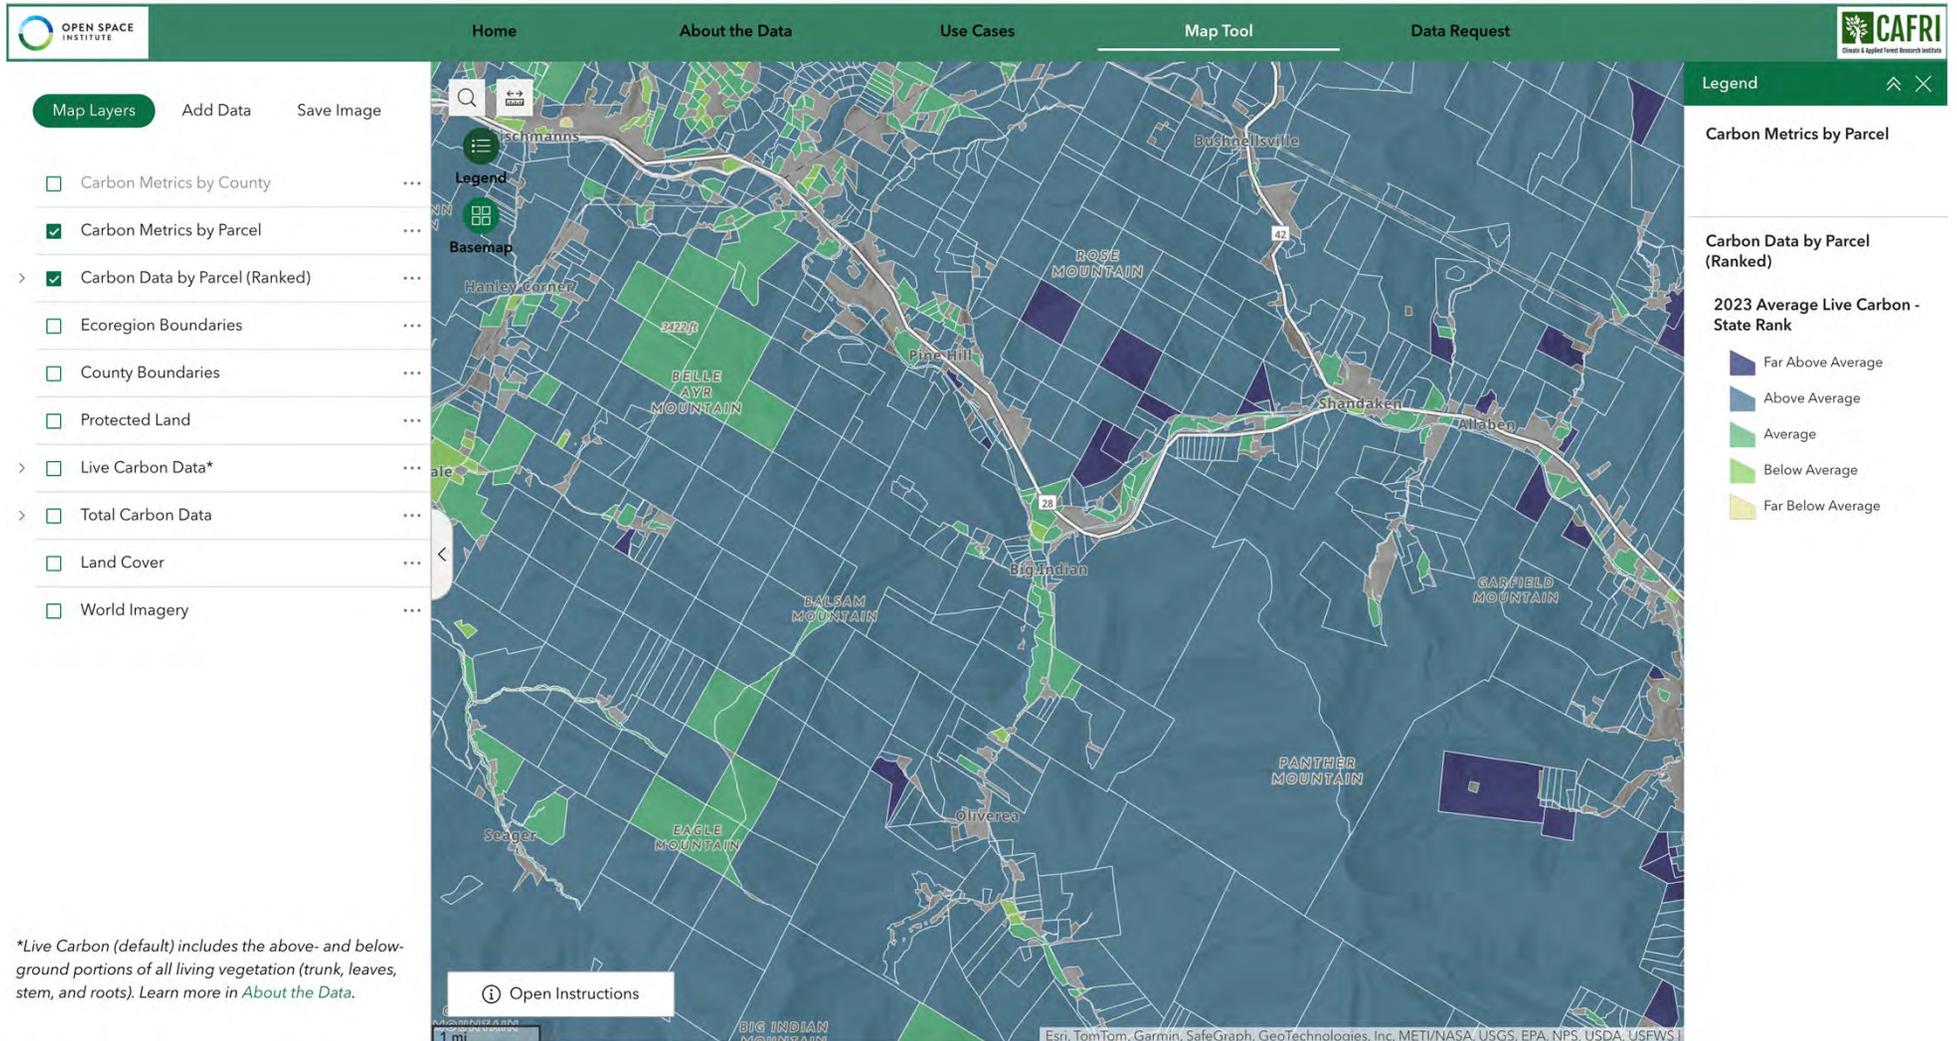

### At-Risk Forest Carbon Stocks

Target land acquisitions to protect C stocks

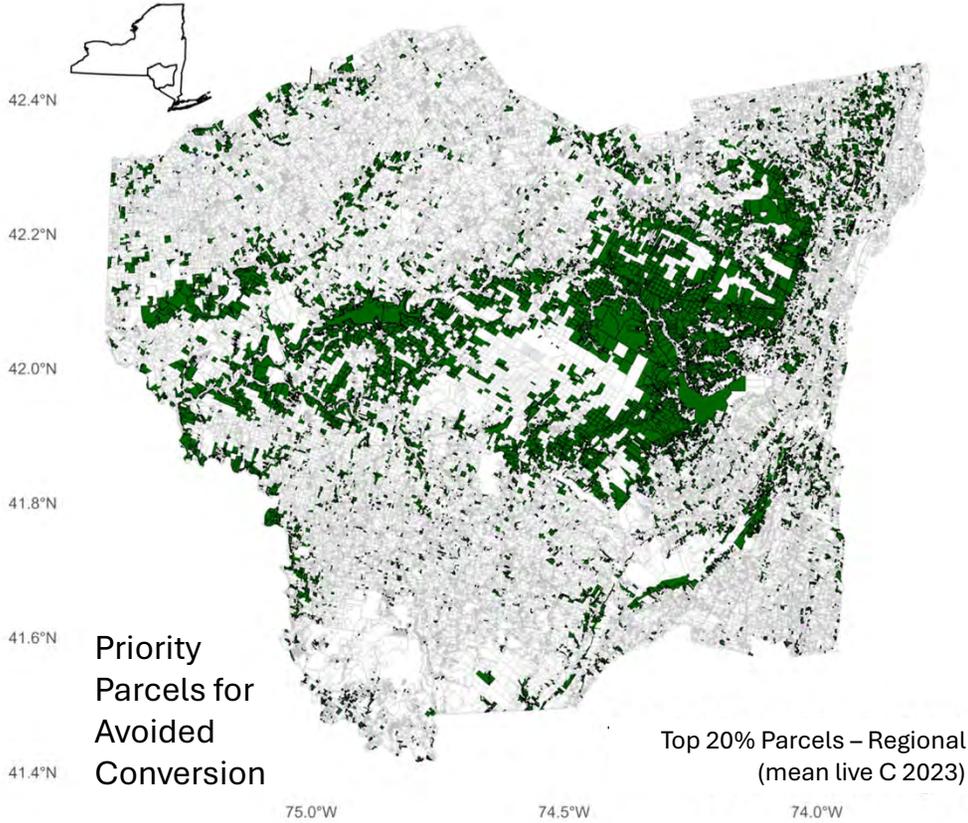

## Applications: Avoiding Conversion

Combining maps of current forest C stocks and forecasts of future land use change can support targeted conservation actions (fee purchase, easements) that maximize overall climate benefits. Future land use is very difficult to predict – scenarios can help explore this uncertainty.

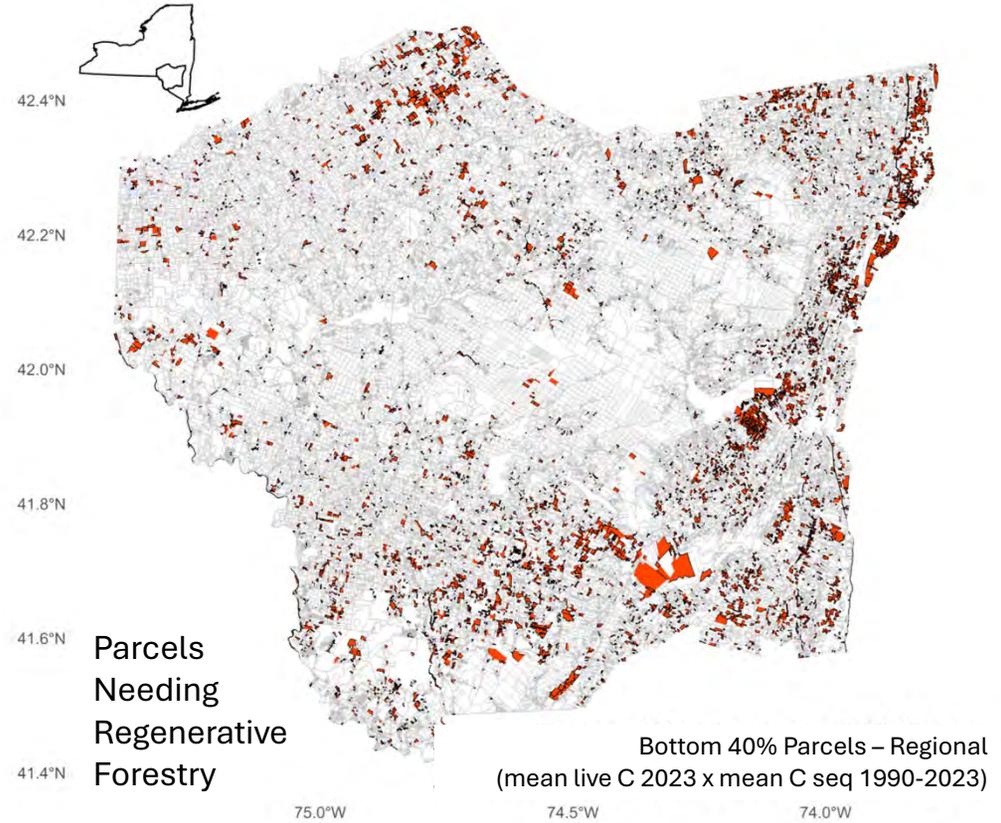

# OSI-CAFRI New York Forest Carbon Map

### High Carbon Density

### Poorly Stocked & Slow Growing

**Applications:  
Screening & Prioritizing Forest Parcels**

## Parcels

---

Screening and prioritizing forest parcels for enrollment in voluntary programs, conservation easements, land trust acquisitions, offsets, etc.

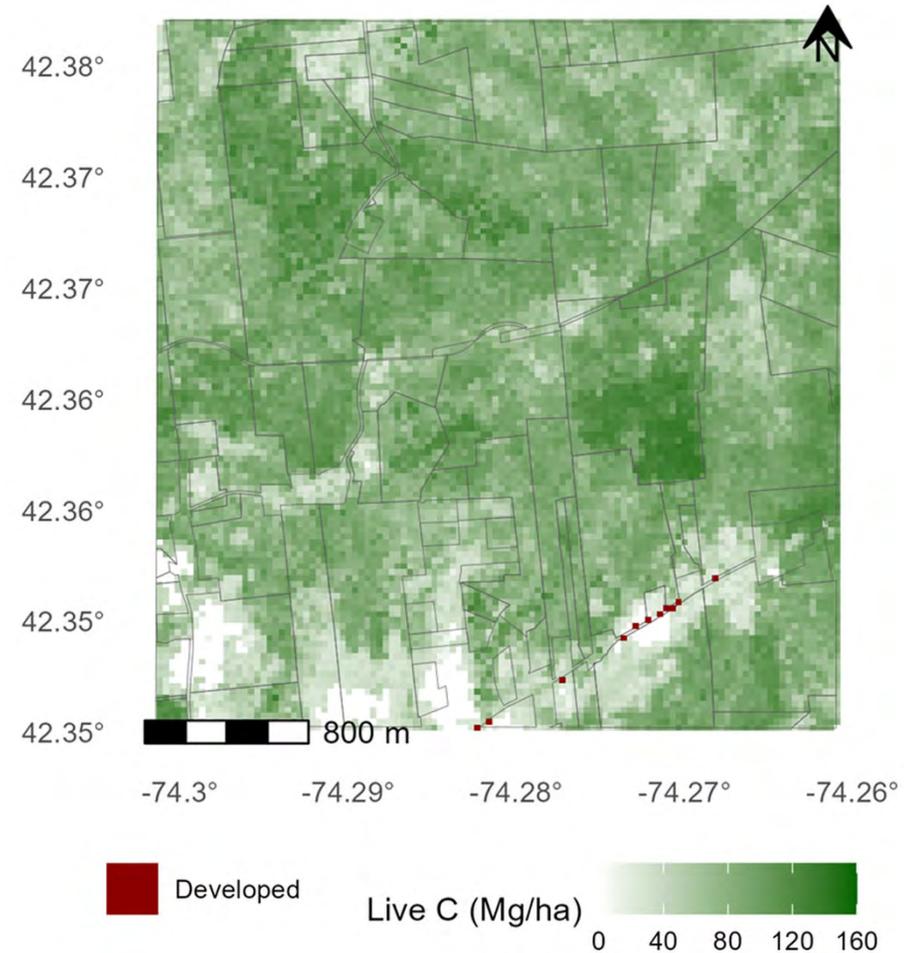

## MMRV

---

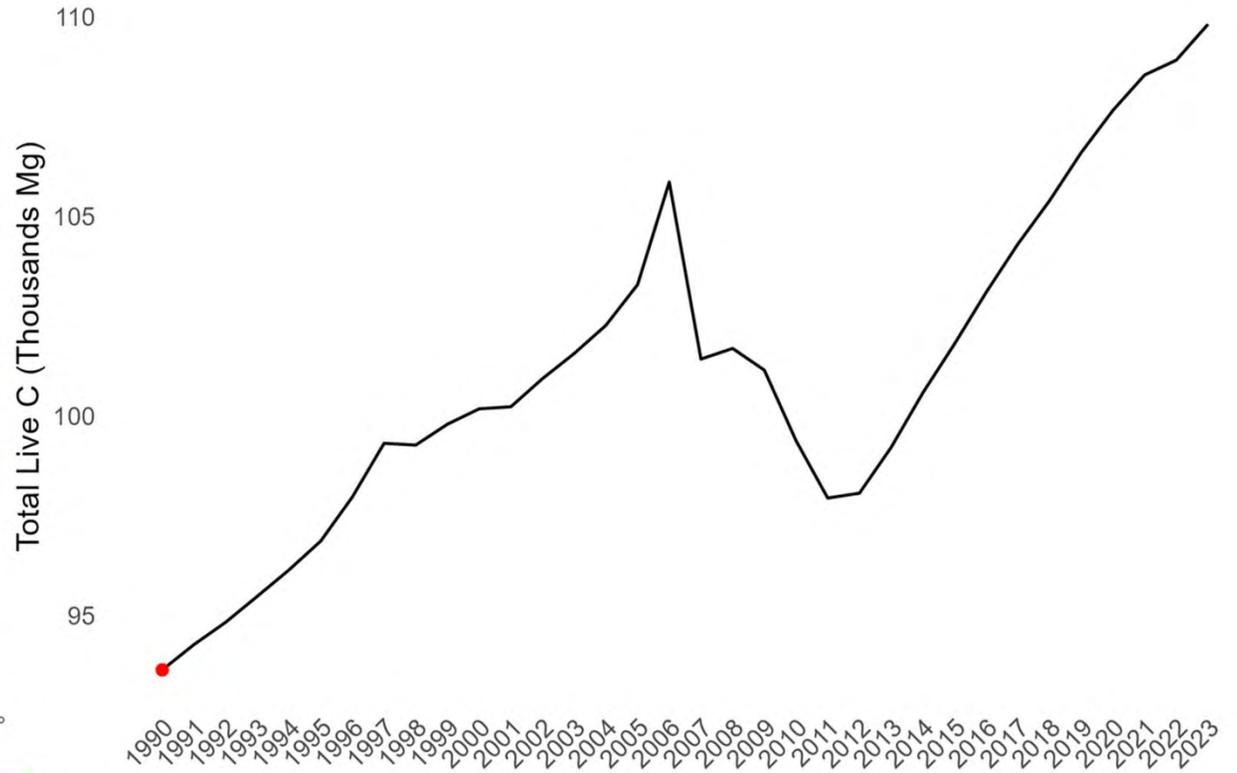

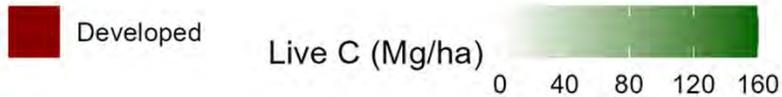

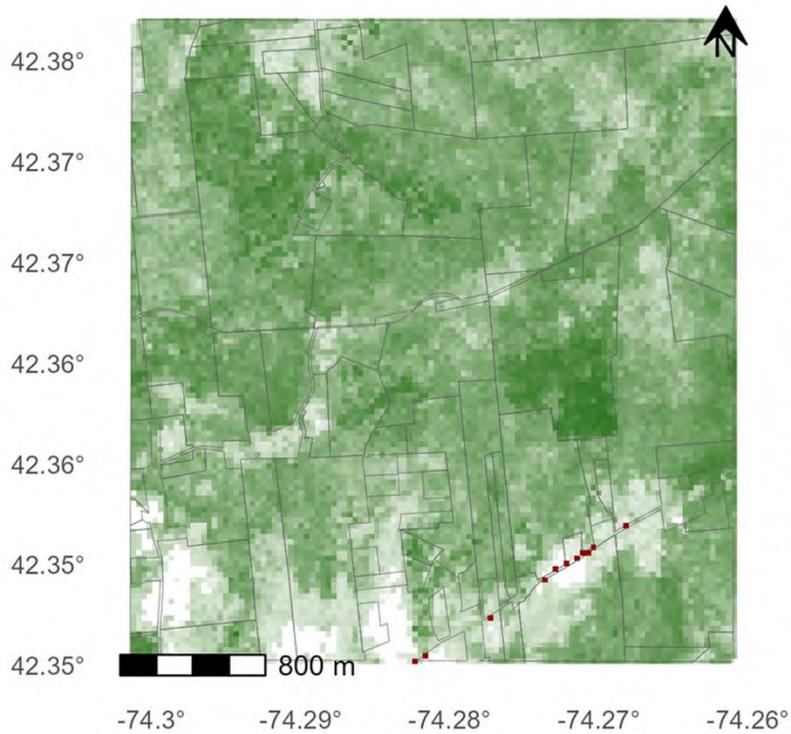

Statewide monitoring provides an efficient basis for tracking C benefits and parcel-level compliance with easements, C offsets, tax abatement programs, etc.

# Applications: Climate Solutions

1990

1990

## Applications: Parcel-level MMRV

- Detection of harvest vs non-harvest disturbances vs land use change
- Estimate harvest volumes, assess post-harvest regeneration vs conversion
- Broad set of applications to support existing and emerging programs

Recent history of forest conditions and land use/land cover changes at parcel scales

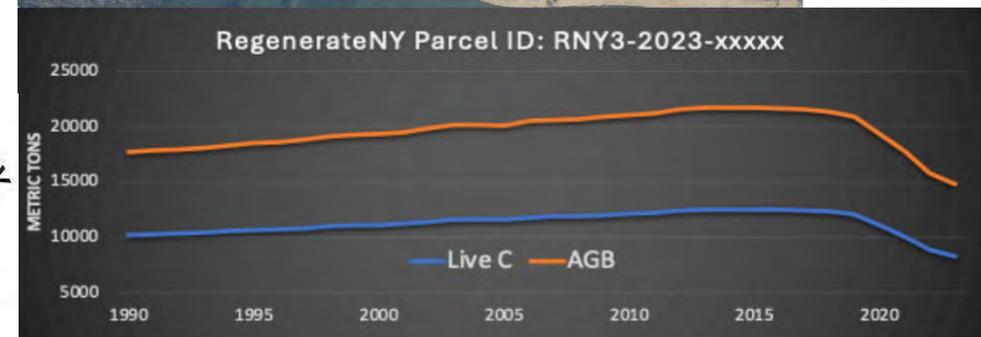

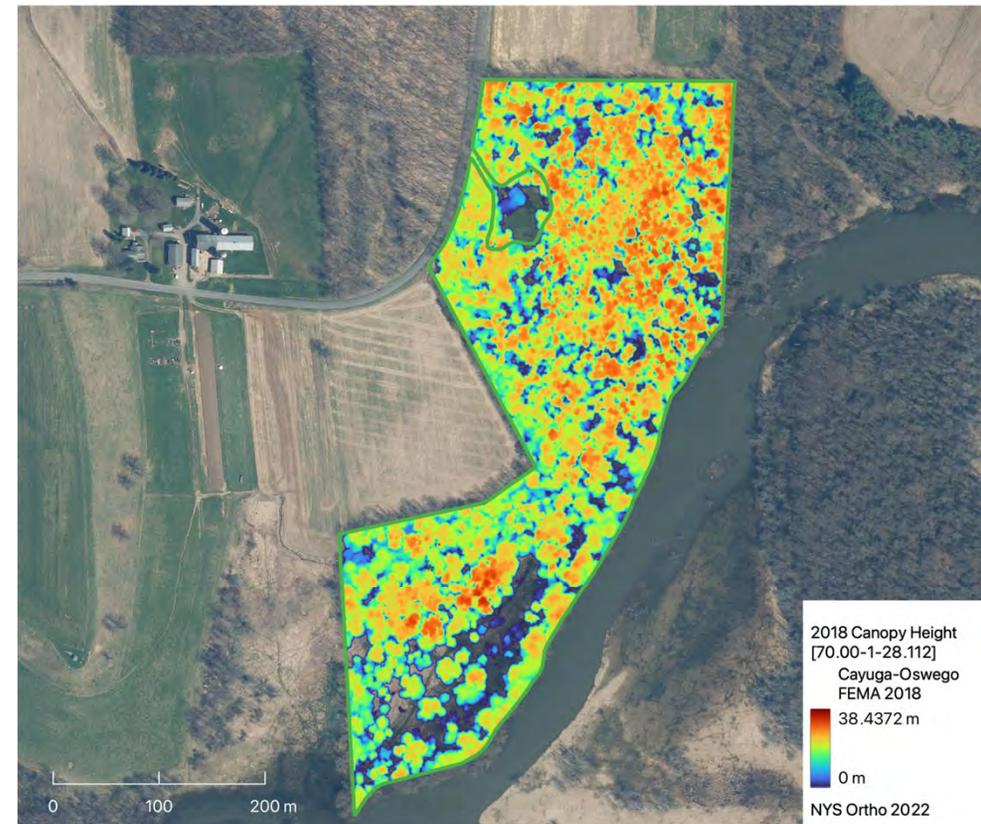

Provides efficient and consistent high-level monitoring to assess program outcomes and prioritize DEC's on-ground compliance efforts

**Forest Tax Law 480a:** verify forest management practices (timing, location, type) and identify any land use conversions in non-compliance

**Regenerate NY:** estimate climate benefits of regenerative forestry practices and monitor progress in reforested areas

Provide landowners and consulting foresters with maps, data products, and annual monitoring updates for enrolled properties

**Applications:  
Parcel-level MMRV**

## Parcels

Screening and prioritizing forest parcels for enrollment in voluntary programs, conservation easements, land trust acquisitions, offsets, etc.

## MMRV

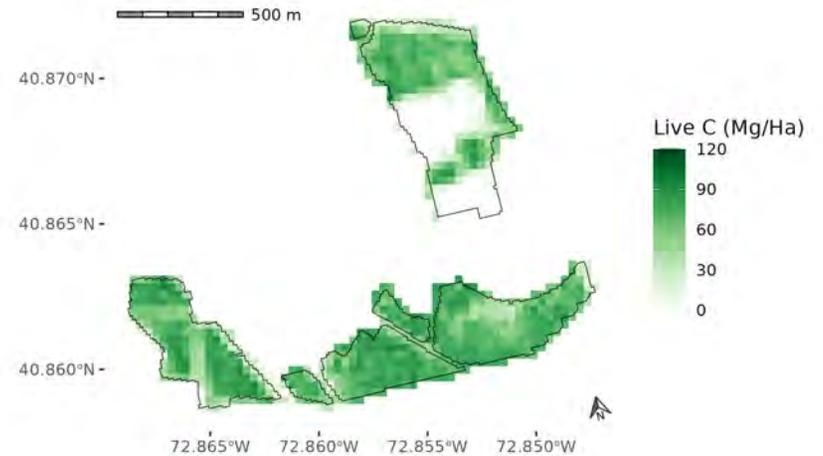

Statewide monitoring provides an efficient basis for tracking C benefits and landowner compliance with easements, C offsets, tax abatement programs, etc.

## Solar

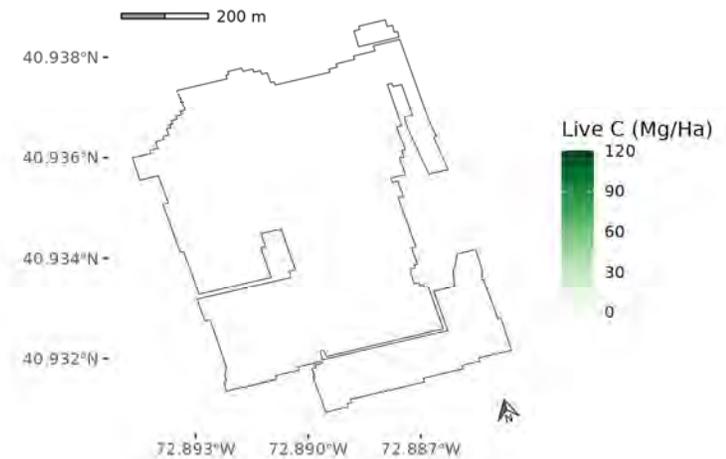

Rapid assessment of proposed solar facilities for New York's Solar Scorecard, to minimize forest loss, C emissions from land clearing for solar farms

## Data Products

**NOW  
AVAILABLE:**

**Model versions 2.0 (AGB, AGC, BGC)**

- 'new' FIA datasets (NSVB)
- Landsat collection 2

## Summary

Catskills region is essential to current and future NYS carbon sink.

Many areas of secondary forest in region ‘hit their stride’ in terms of growth and **C sequestration** over the last few decades.

Moderate-to-high carbon density forests with ample potential for future sequestration exist on **both public and private lands**.

Younger ‘patchy’ forests on private lands contribute much to regional C sink, but are also more **vulnerable** to degradation/loss.

**Regenerative forestry** needed to grow and sustain future regional C sink beyond 2050... while providing many other co-benefits.

**Avoiding conversion** is first priority... then local **stewardship** to sustain productivity, address threats, build adaptive capacity.

Data products & tools **available now** ... and more in the works.

**CAUTION!!** This talk was produced in a facility built to support science-based decision-making and may contain:

- 1. (Very) Applied Research**
- 2. Data Mining (Modeling for Prediction)**
- 3. Limited Gory Details**

# Approach

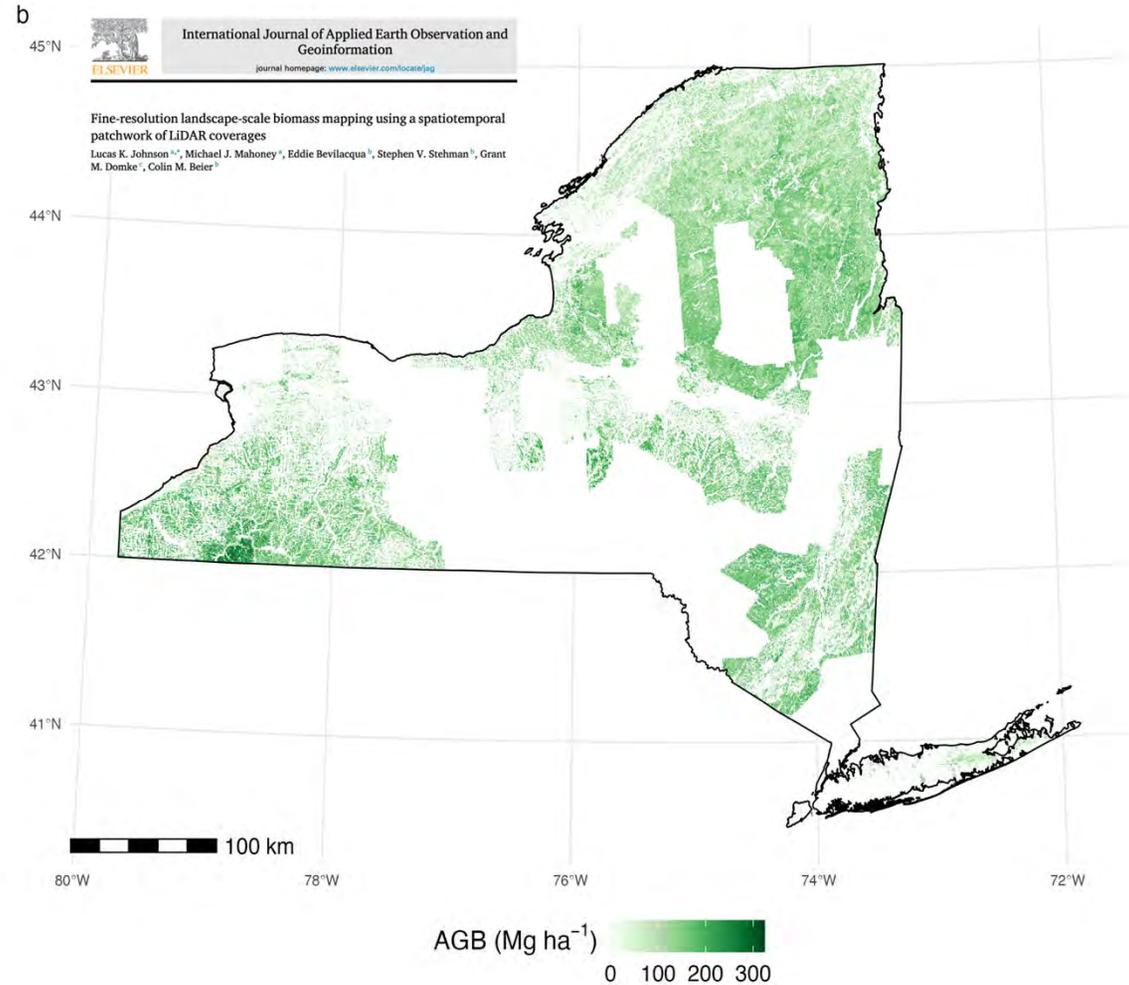

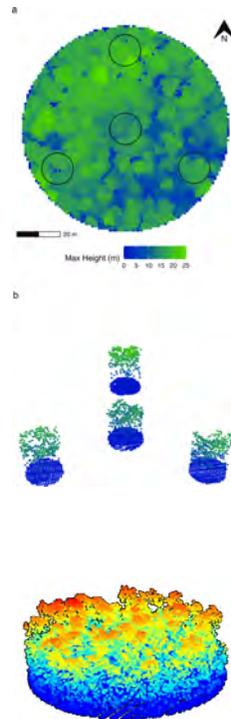

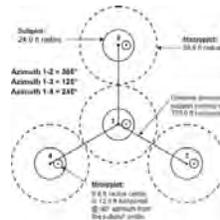

Use ML models to map forest aboveground biomass (AGB) for LIDAR year at 30m resolution

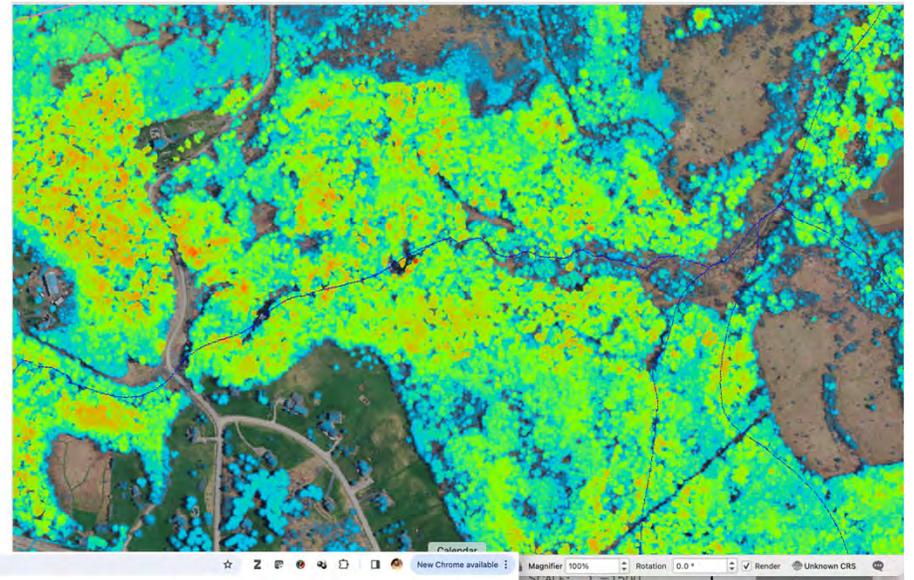

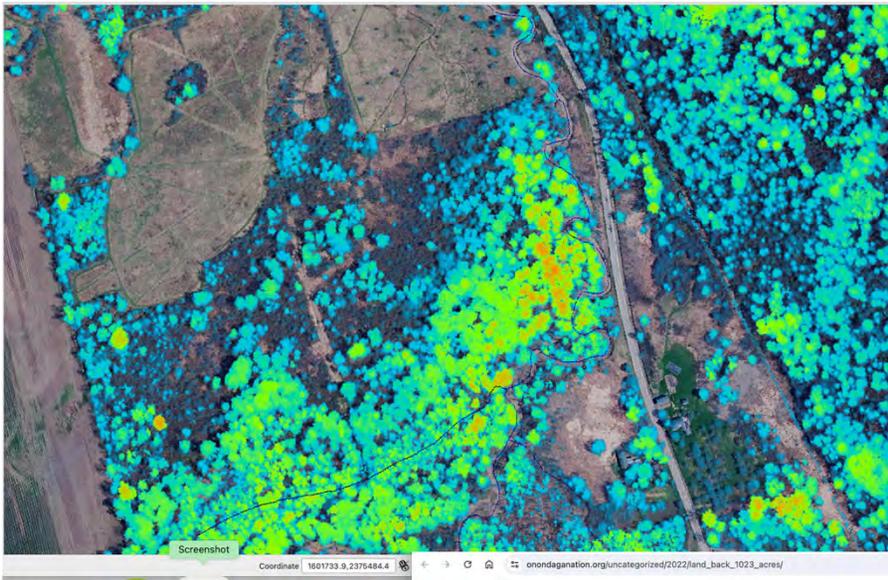

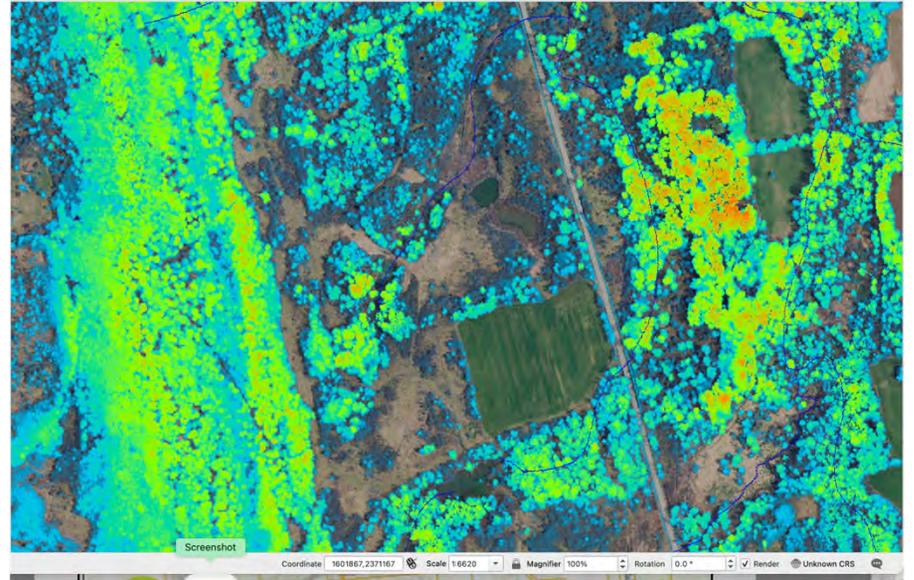

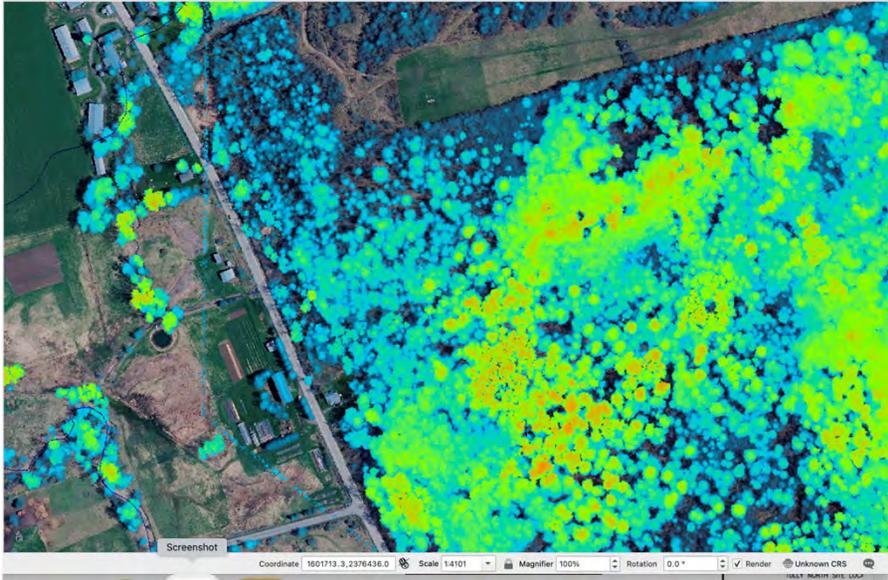

LIDAR offers highest accuracy at landscape scales, however:

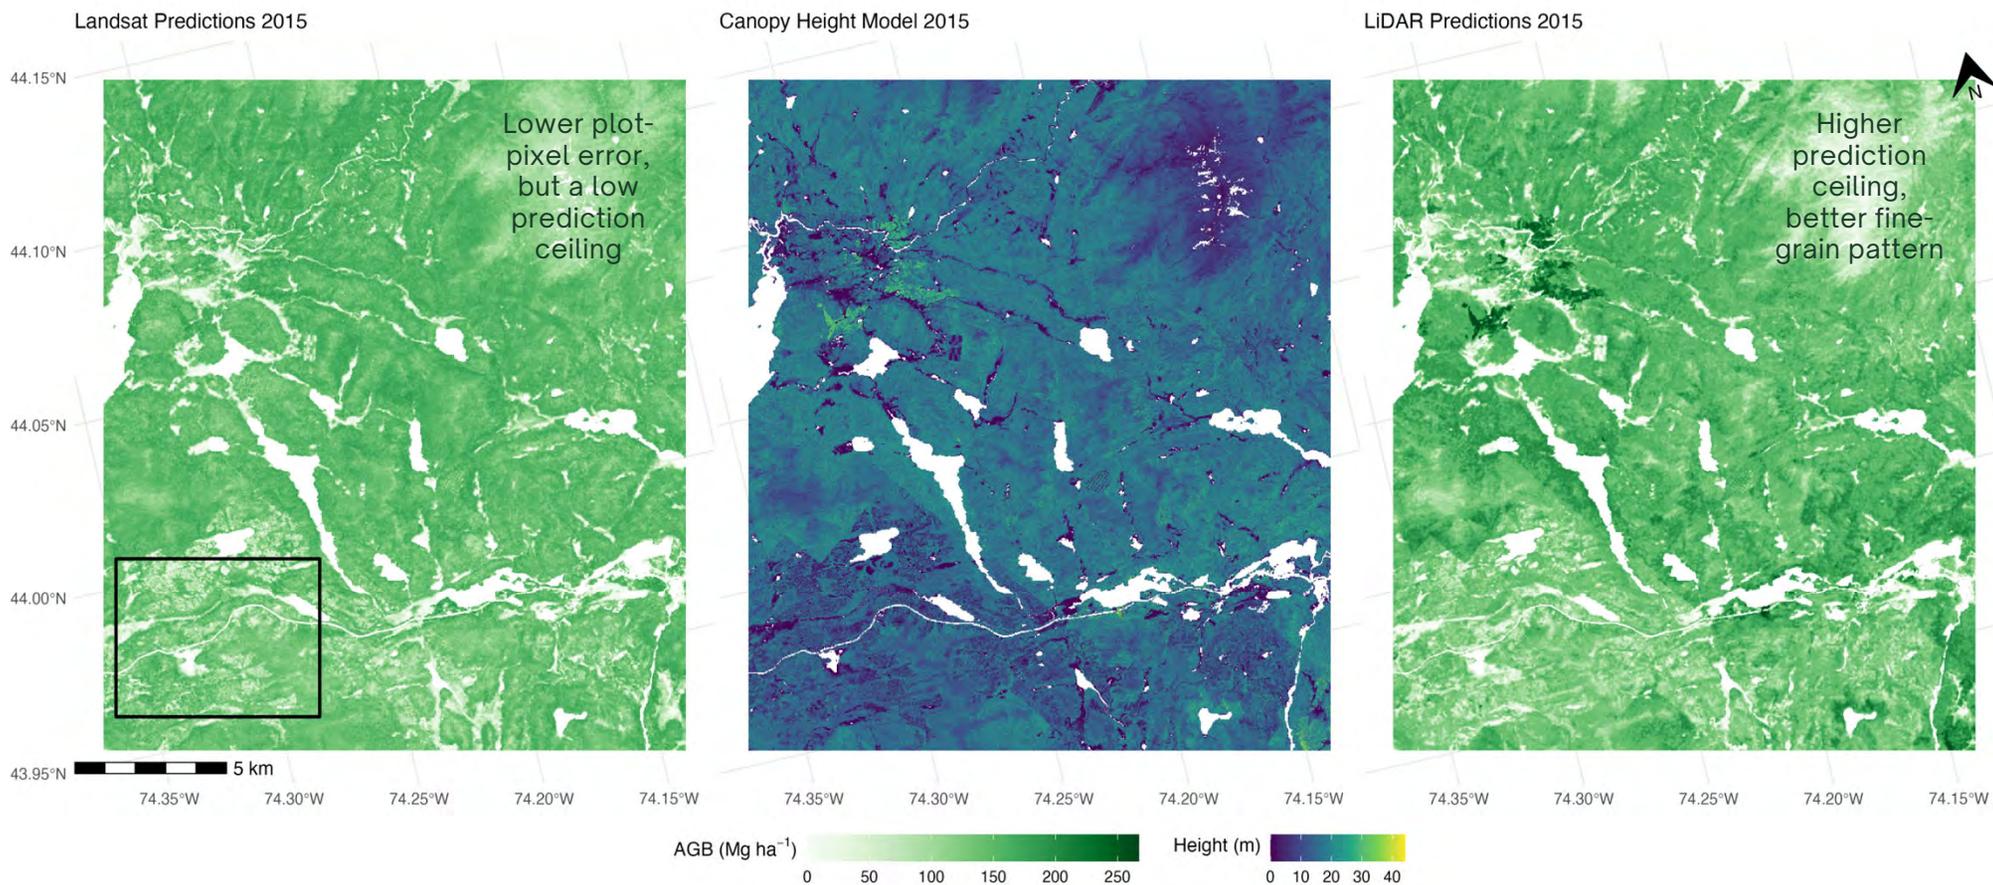

- Snapshot in time
- Disparity among sensors, mission parameters, etc. can result in 'lost' info
- Very limited areas with multitemporal coverage
- Computationally intensive

LIDAR maps alone not sufficient for stock-change analysis or related needs & applications

**AGB & C Mapping**

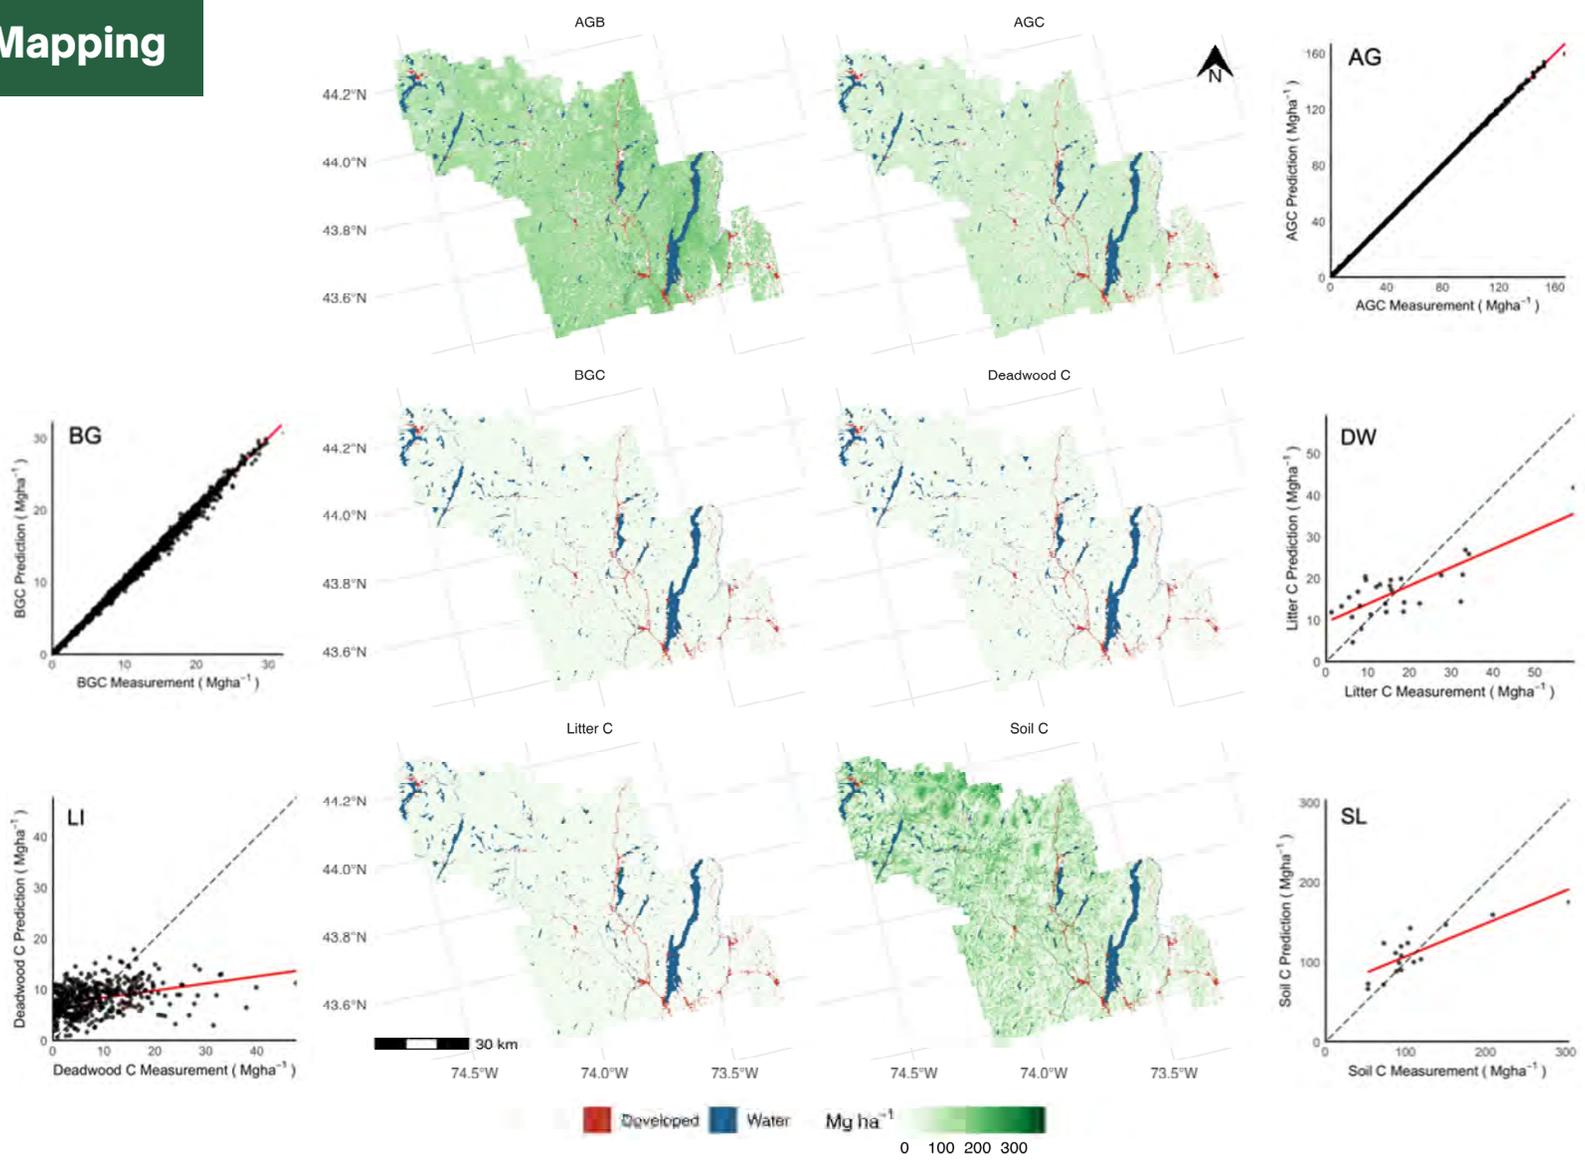

## AGB & C Mapping

Hybrid ensembles combine direct (Landsat x FIA) and indirect (Landsat x LIDAR-AGB) using a common set of LT-GEE derived predictors to achieve a good balance between overall accuracy, prediction ceiling and fine-grain patterns.

## AGB & C Mapping

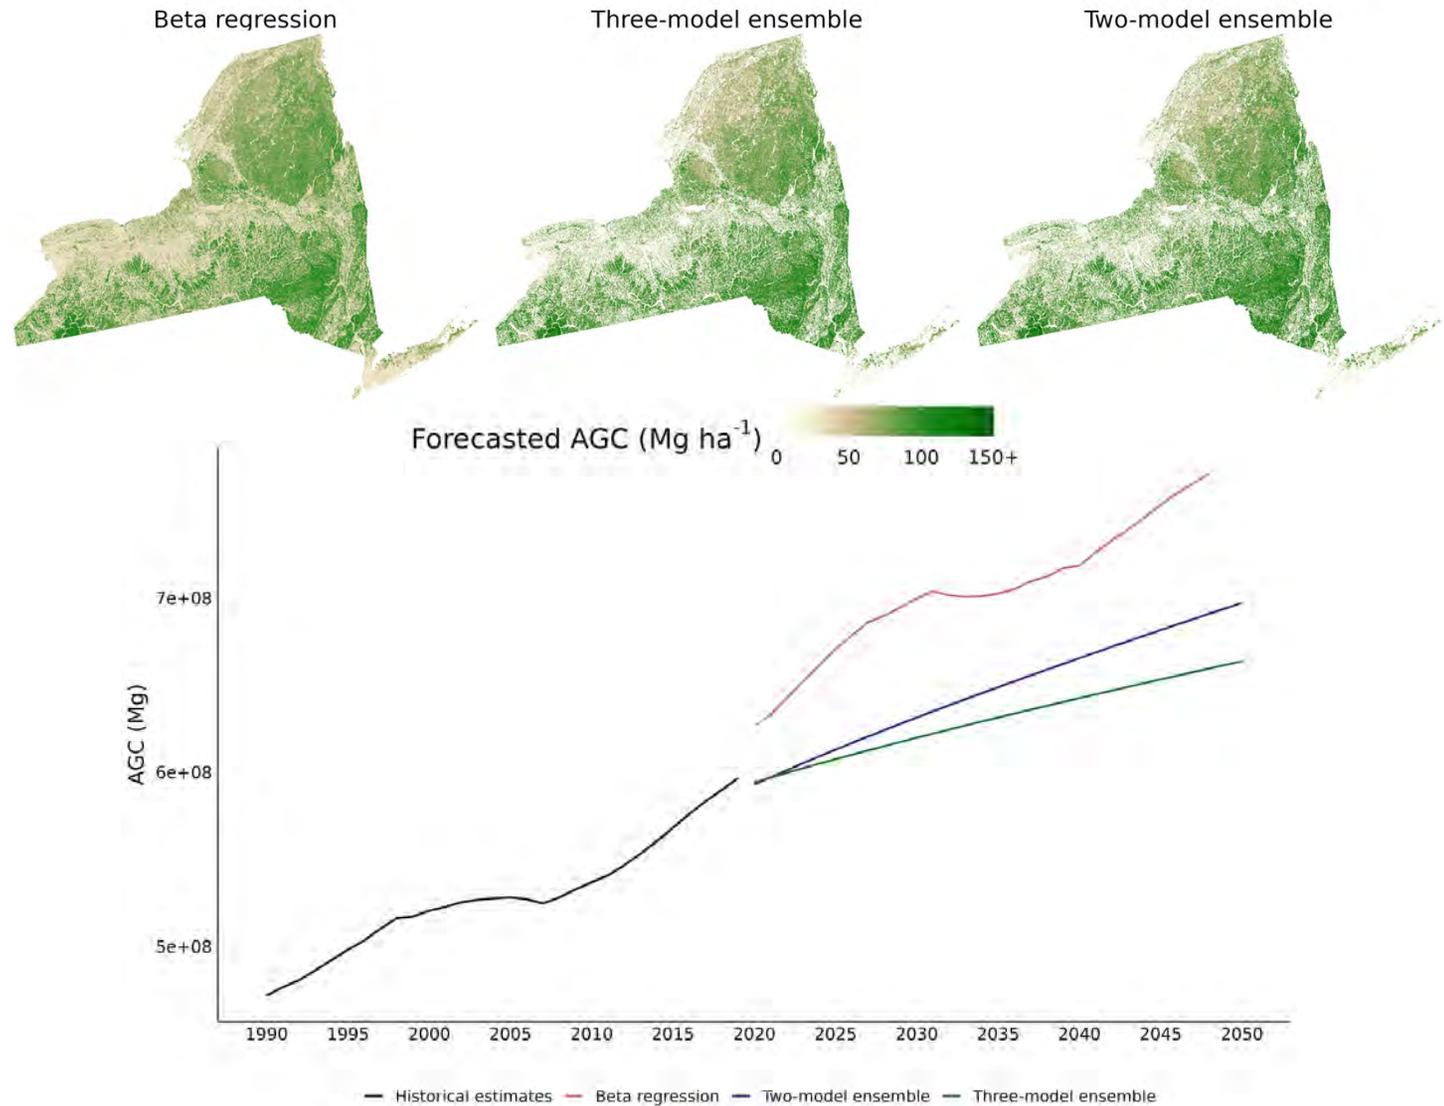

Time-series forecasting models trained on historical map series at pixel level

Baseline or 'business as usual' map forecasts of potential future C seq

Many forecasts possible...

Can incorporate future LULC maps and model scenarios

Next step: integrate stand-level simulations (FVS) into mapping framework

**Forecasting**

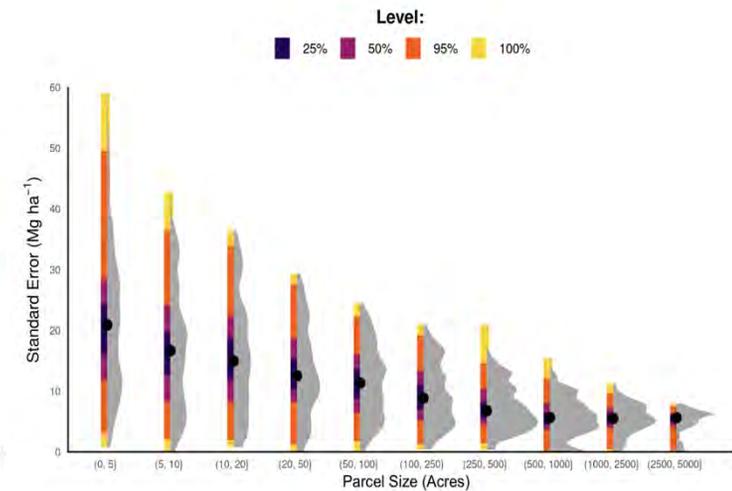

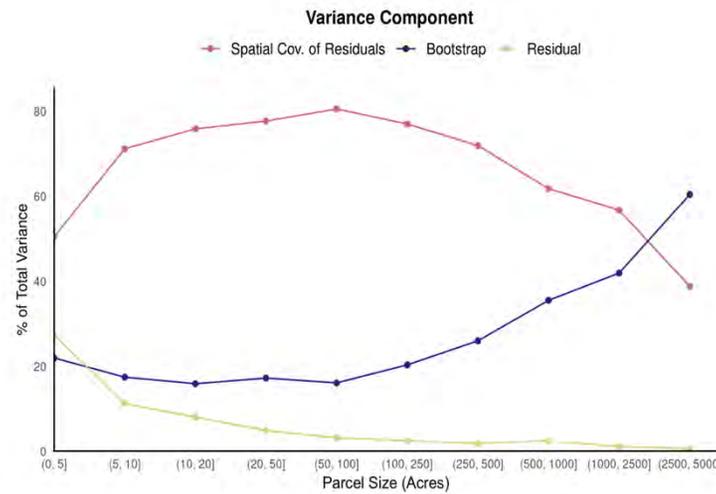

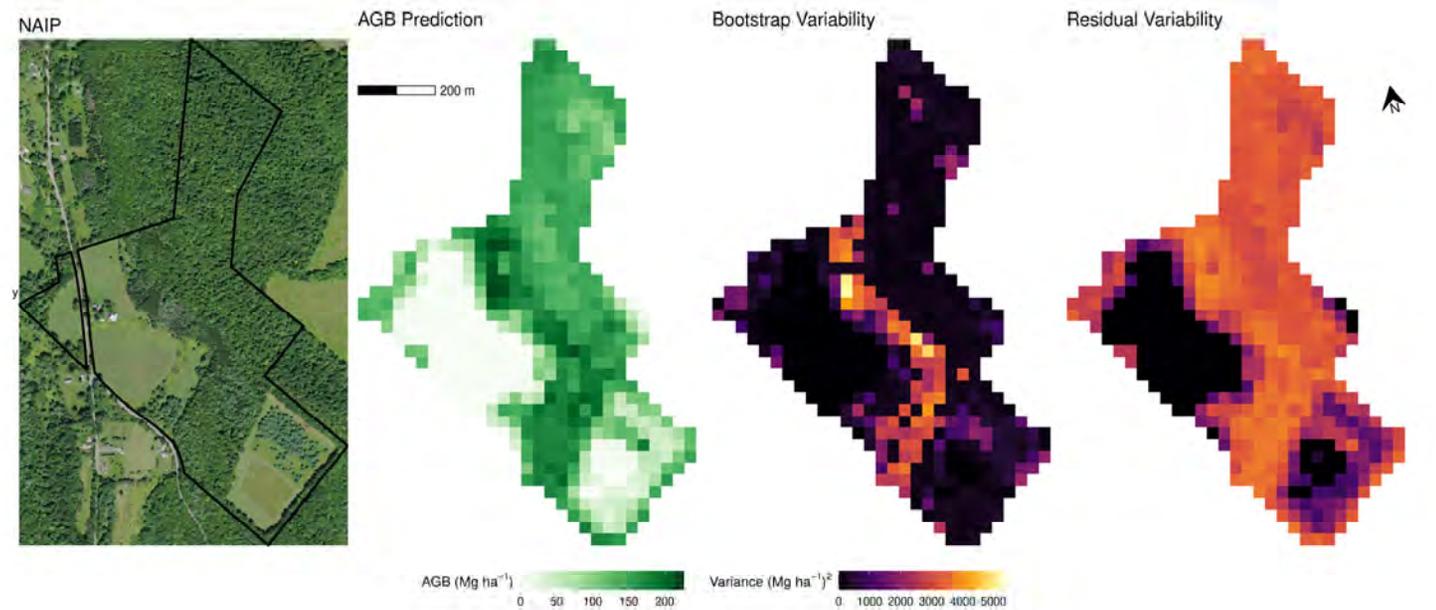

Compiled most known sources of uncertainty in modeling framework:

- Inventory plot location
- Plot measurement error
- Allometric models
- Spatial model residuals
- Spatial covariance

Error propagation through 'daisy-chain' of models

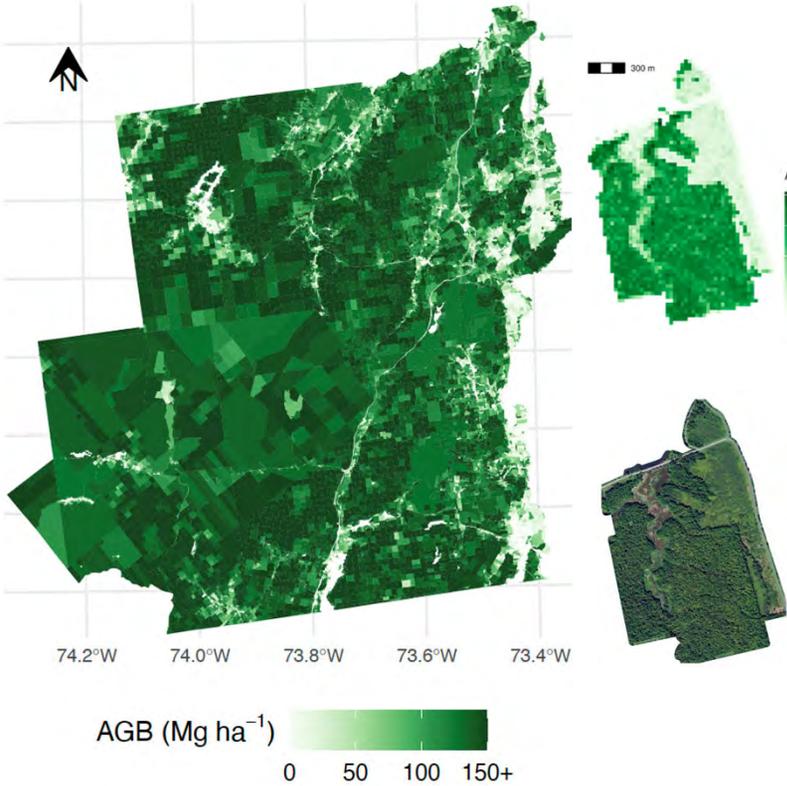

Provides pixel-level estimates of variability for map products

Scaleable uncertainty estimation for arbitrary map areas (groups of pixels)

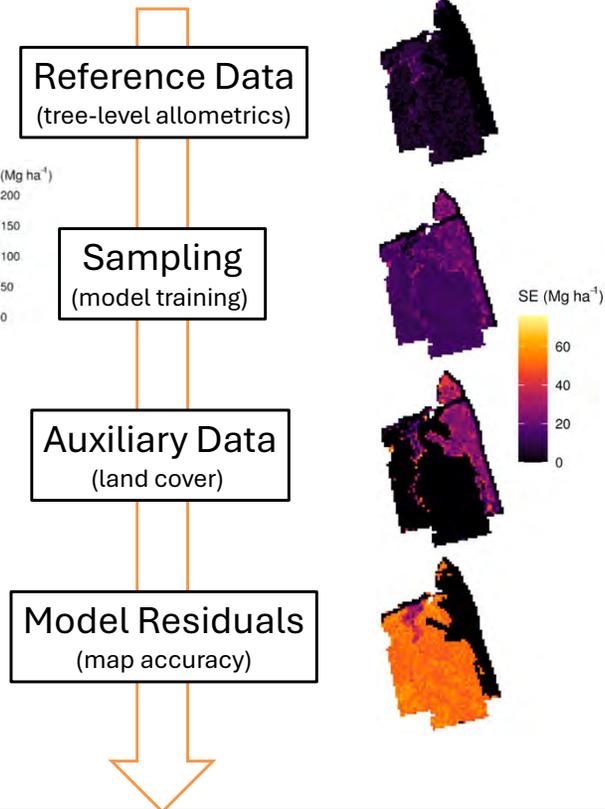

**Uncertainty**

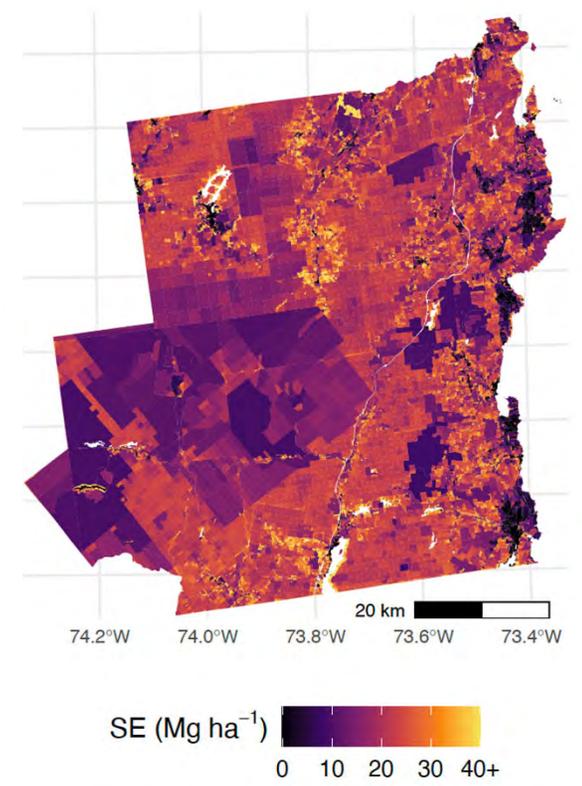

Mean Aboveground Biomass (AGB)  
Density by Parcel

### Types of Uncertainty

Standard Error (SE)  
Mean AGB Density by Parcel

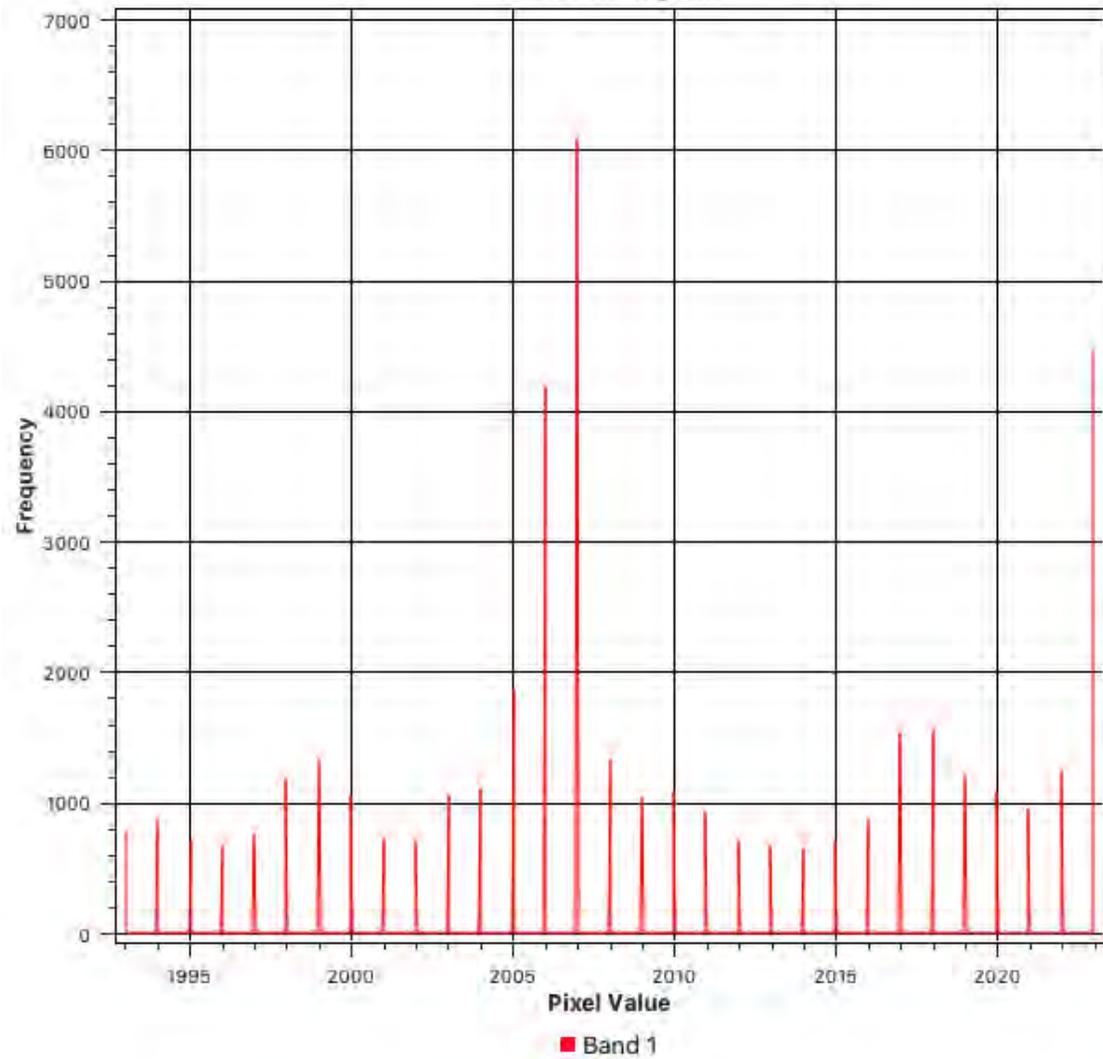

Spatial Averaging  
(by parcel)

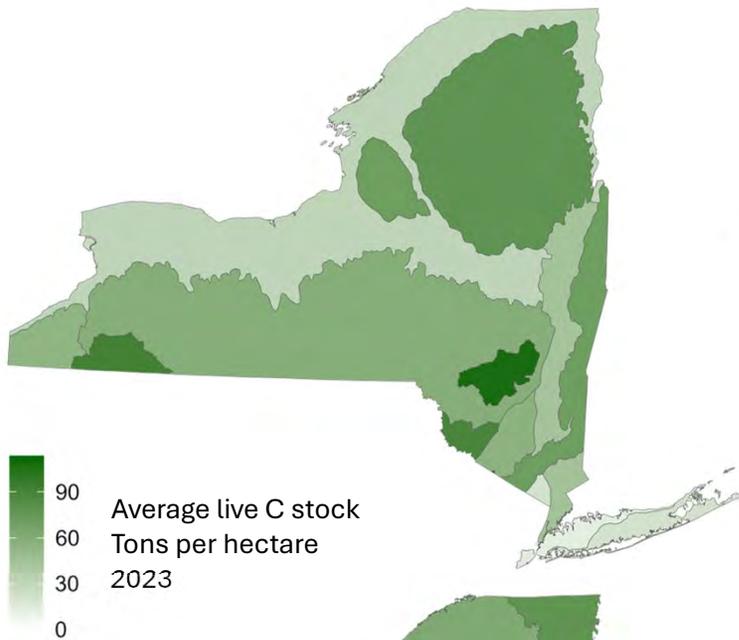

Bootstrap Resampling  
(pixel-level uncertainty)

Least Squares Regression  
(mean AGB, % cover, size, shape)

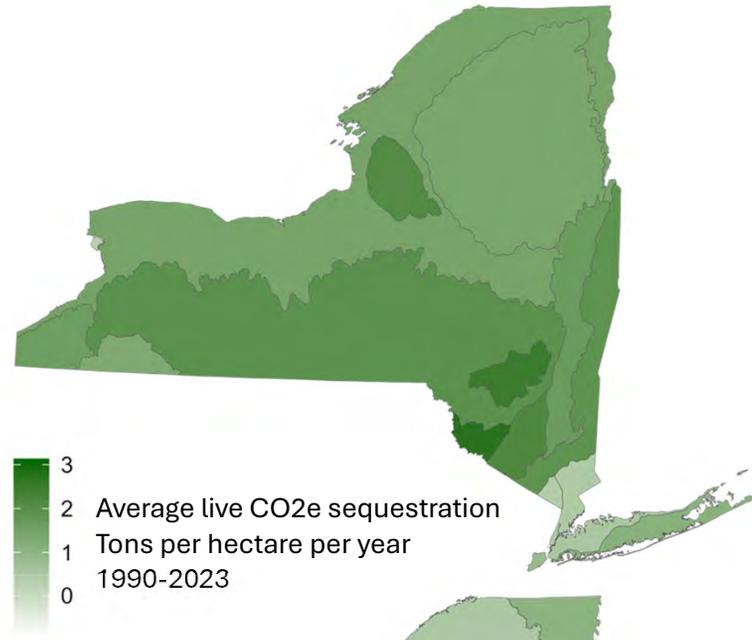

Raster Histogram

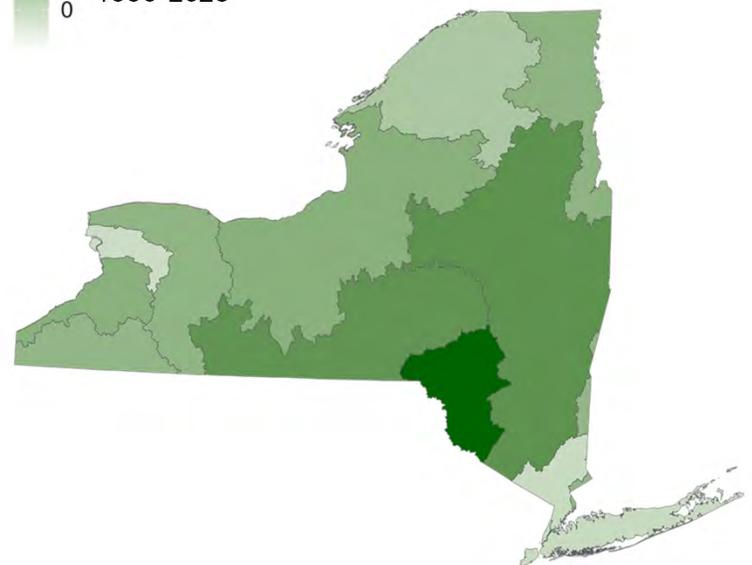

# Role of Catskills in NYS Carbon Sink

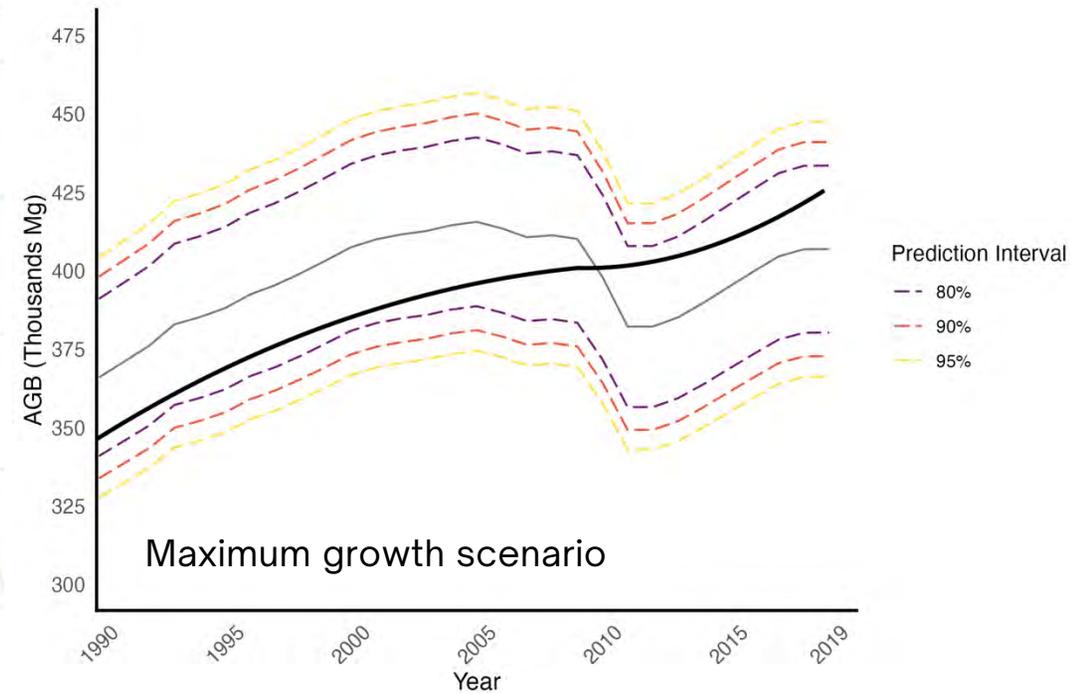

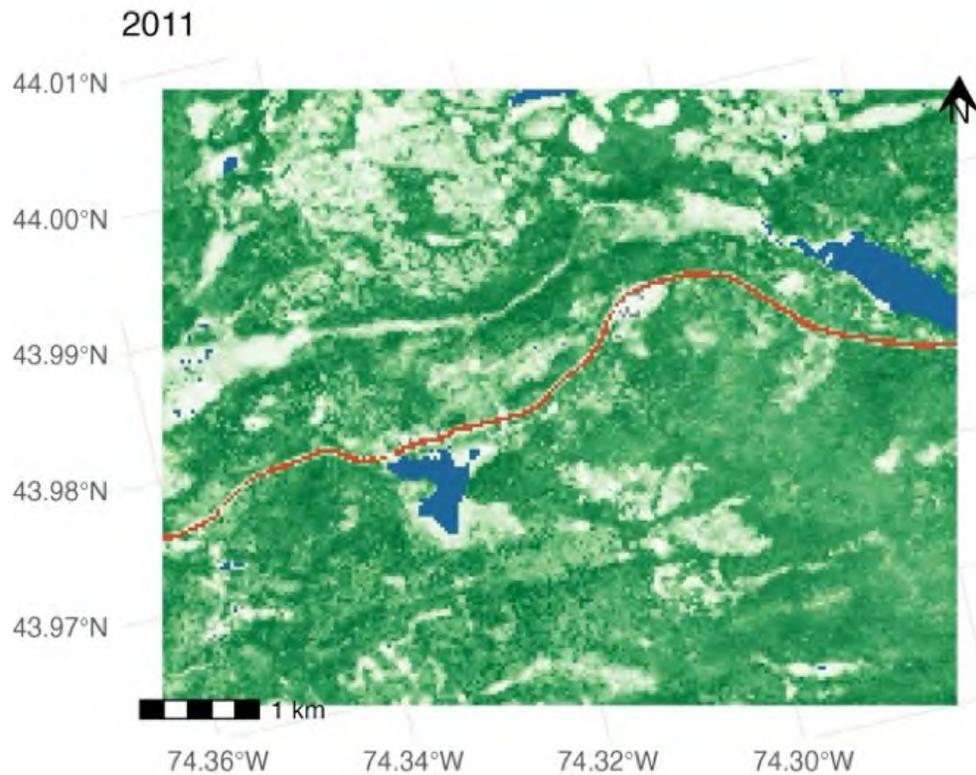

By Ecoregions  
(Level III)

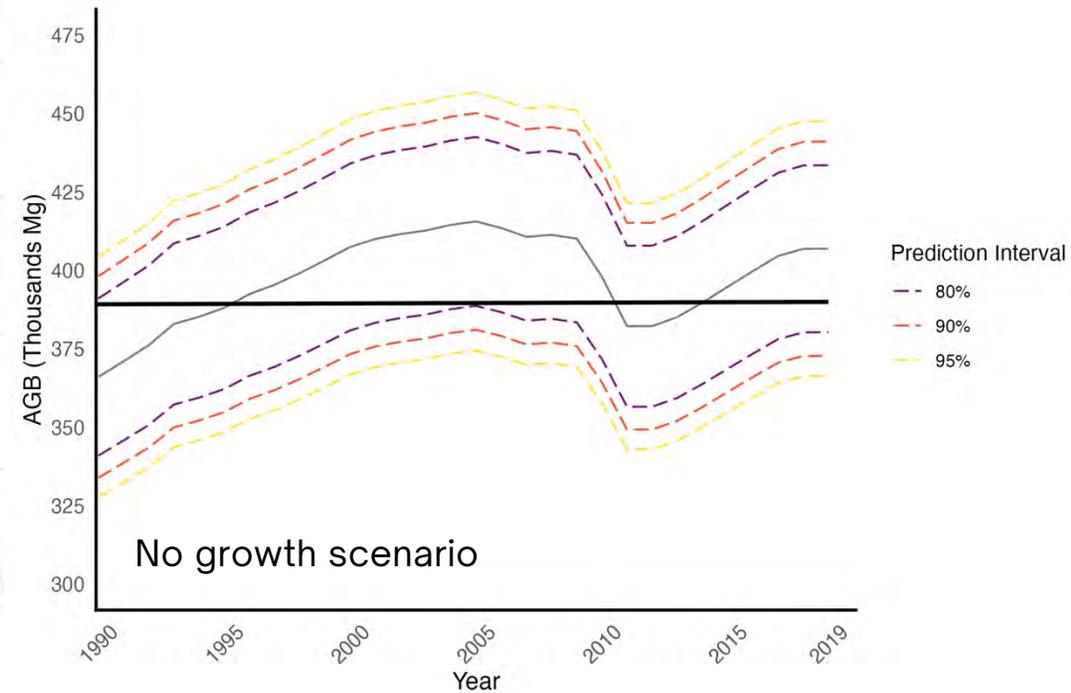

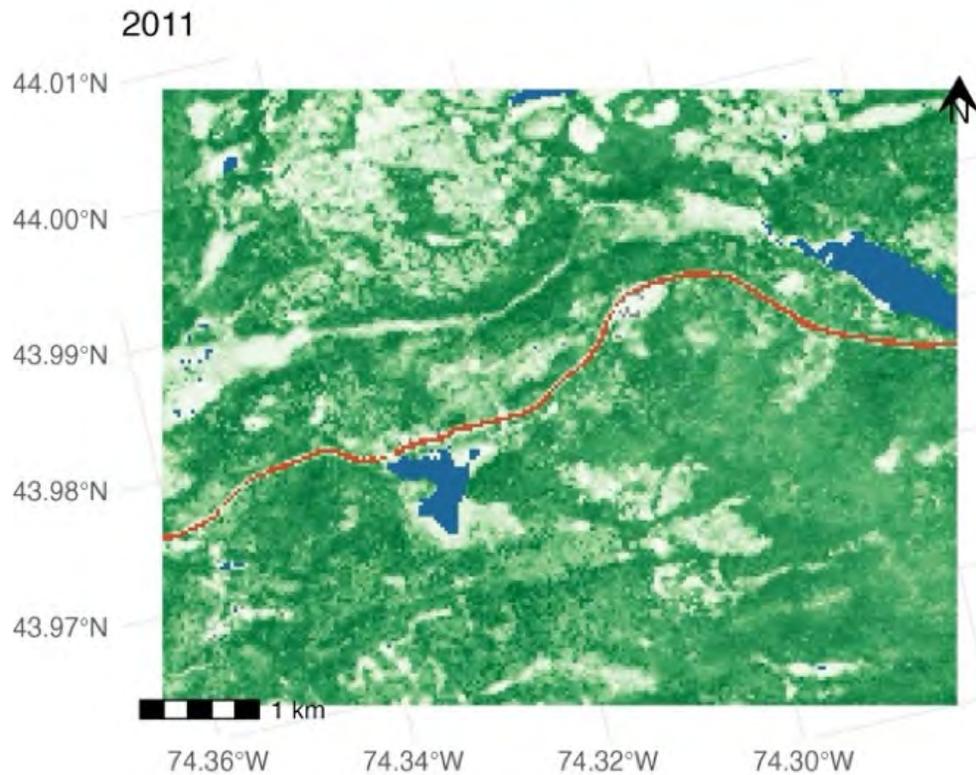

By Watersheds  
(Basins)

## Uncertainty

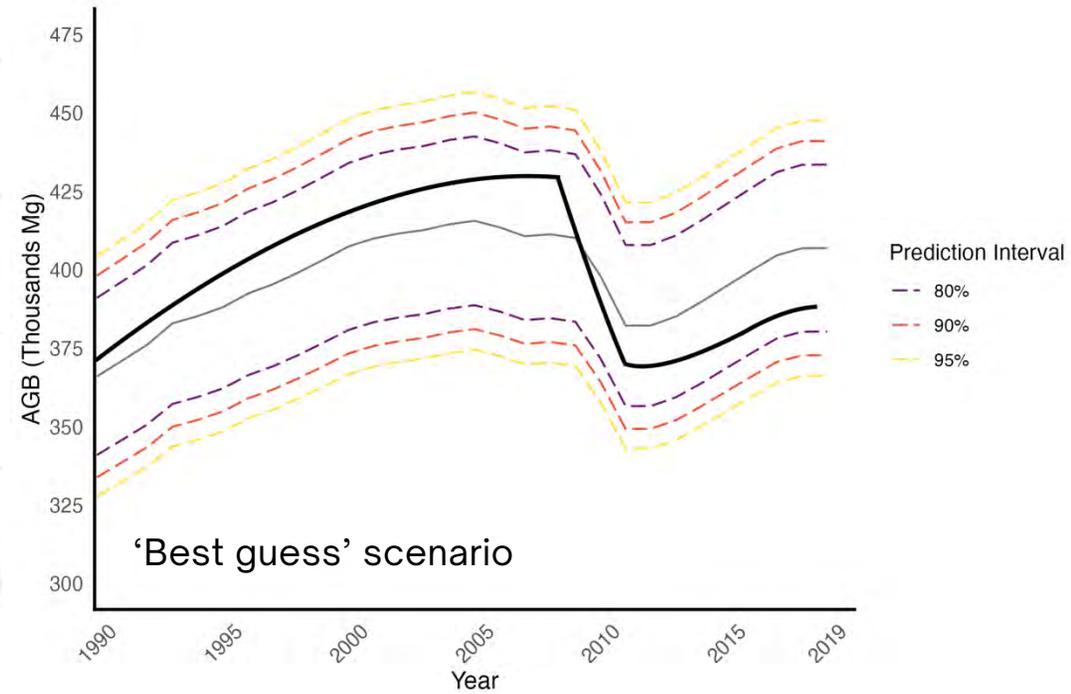

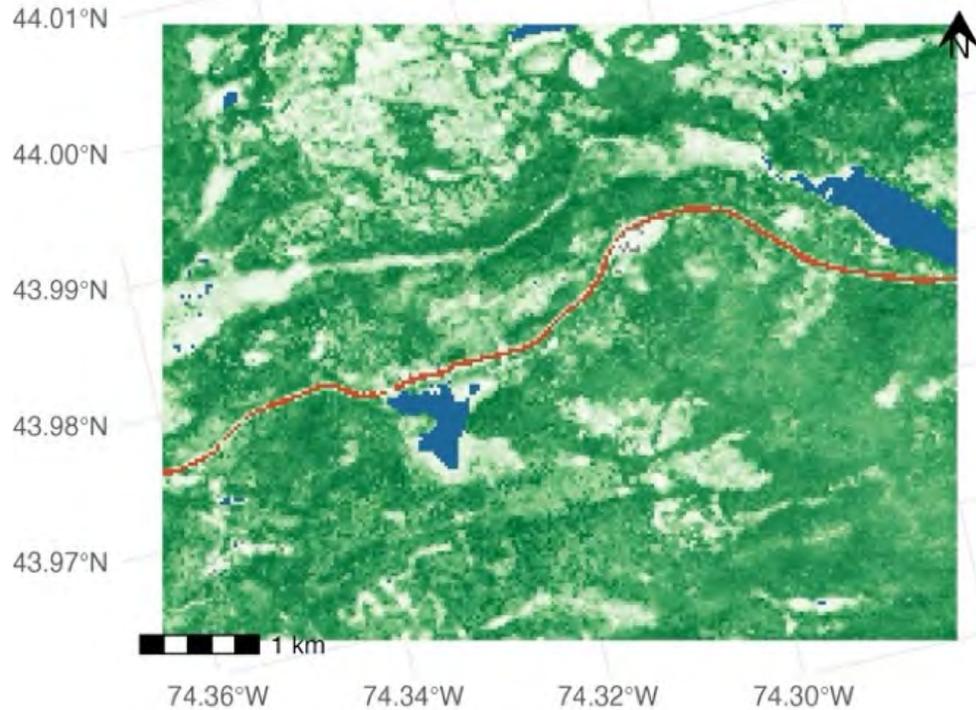

Can we reliably estimate stock-changes when uncertainty > rate of change?  
 Even with "best in class" models (h/t: J. Battles) there is room for interpretation  
 Room for improvement: reducing uncertainty, 'green up' vs 'grow up', etc.

## Uncertainty

Can we reliably estimate stock-changes when uncertainty > rate of change?  
 Even with "best in class" models (h/t: J. Battles) there is room for interpretation  
 Room for improvement: reducing uncertainty, 'green up' vs 'grow up', etc.

2011

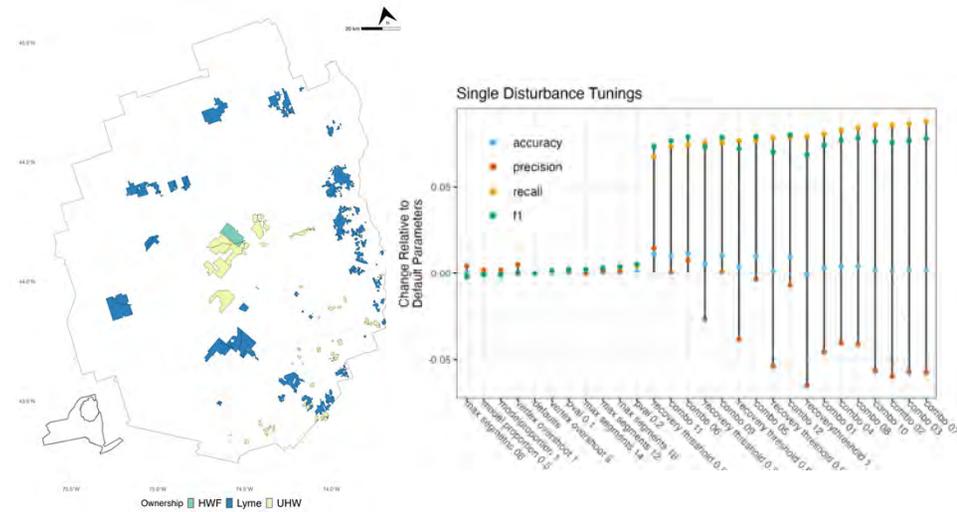

## Uncertainty

Can we reliably estimate stock-changes when uncertainty > rate of change?  
Even with "best in class" models (h/t: J. Battles) there is room for interpretation  
Room for improvement: reducing uncertainty, 'green up' vs 'grow up', etc.

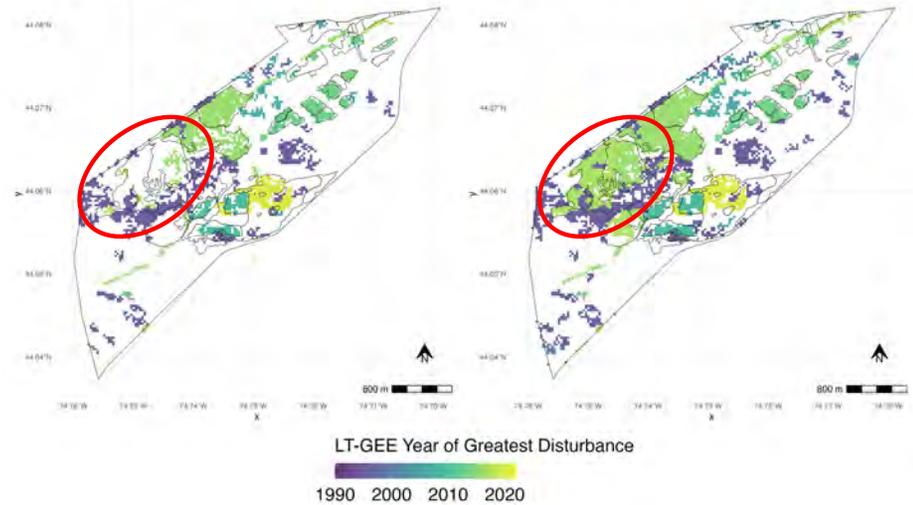

# Detection

Multiple 'tunings' of LT-GEE based on extensive harvest records; provides statewide high-res data on disturbance timing, location, magnitude back to 1990

A. Defaults

B. Combination 6

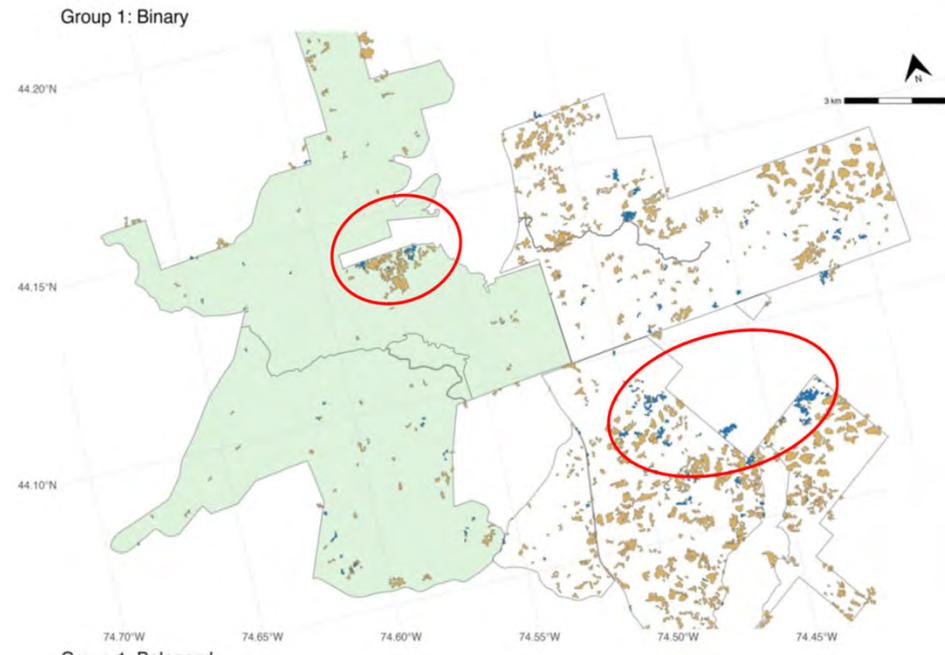

Applications: Landscape Change

## Detection

Multiple ‘tunings’ of LT-GEE based on extensive harvest records; provides statewide high-res data on disturbance timing, location, magnitude back to 1990

## Attribution

Patch level classification of harvest vs non-harvest disturbances based on spectral, spatial properties of LT-GEE outputs

| Accuracy | Precision | Recall | Specificity | F1    | ROC AUC |
|----------|-----------|--------|-------------|-------|---------|
| 0.926    | 0.937     | 0.937  | 0.908       | 0.937 | 0.969   |

| Land Designation |         | Total Area (ha) | Percentage Total Area Disturbed | Disturbed Area Classified as Harvest |
|------------------|---------|-----------------|---------------------------------|--------------------------------------|
| Group 1          | Private | 10,498          | 12.06%                          | 850 (67.1%)                          |
|                  | Public  | 10,692          | 2.45%                           | 30 (11.5%)                           |
| Group 2          | Private | 28,639          | 17.39%                          | 3,339 (67.0%)                        |
|                  | Public  | 28,343          | 3.34%                           | 260 (27.5%)                          |

**Applications: Landscape Change**

## Detection

Multiple 'tunings' of LT-GEE based on extensive harvest records; provides statewide high-res data on disturbance timing, location, magnitude back to 1990

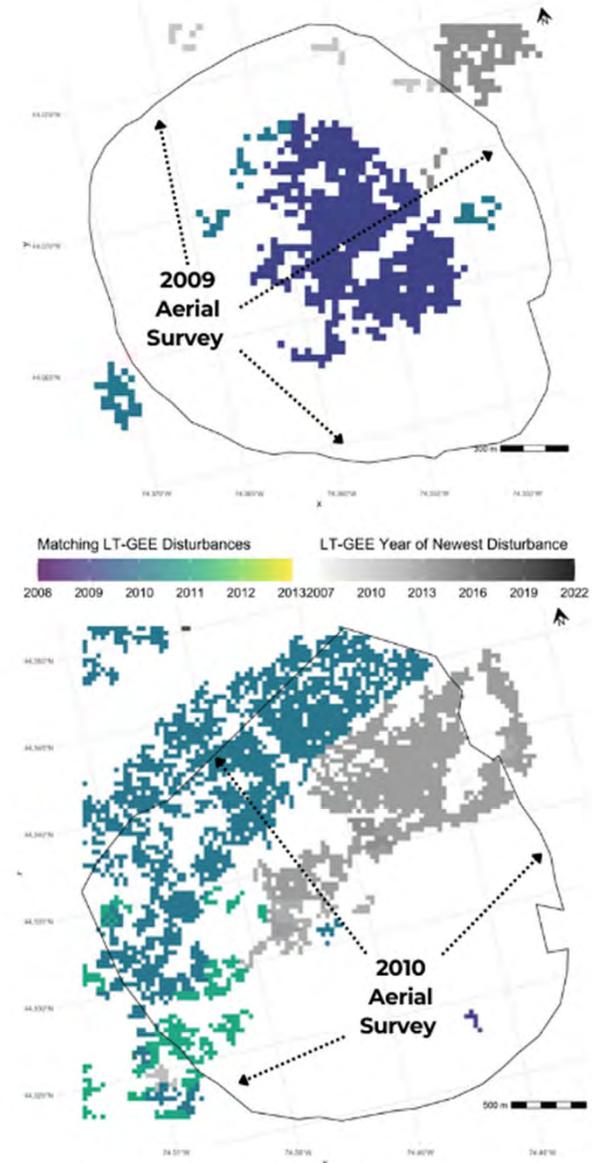

## Attribution

Patch level classification of harvest vs non-harvest disturbances based on spectral, spatial properties of LT-GEE outputs

## Forest Health

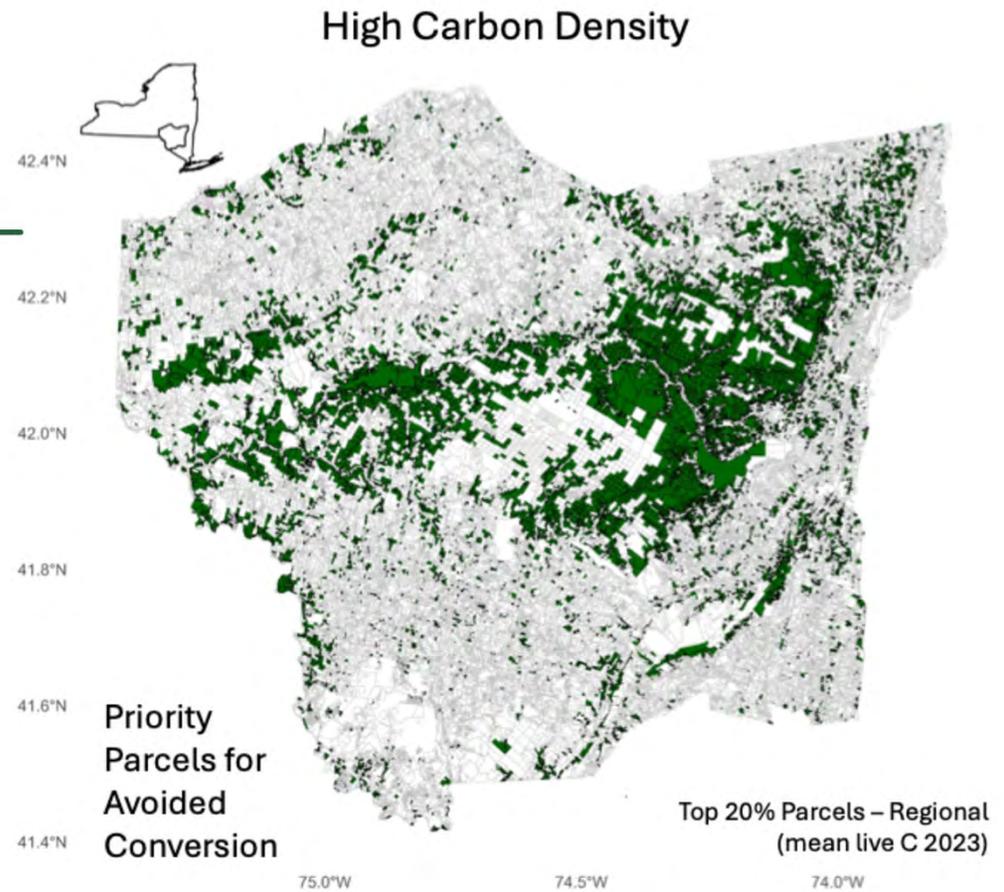

Cross validation of DEC aerial forest health maps; mapping insect outbreaks and pathogen impacts, defoliation events, etc.

**Applications: Landscape Change**

# Parcels

Screening and prioritizing forest parcels for enrollment in voluntary programs, conservation easements, land trust acquisition, offsets, etc.

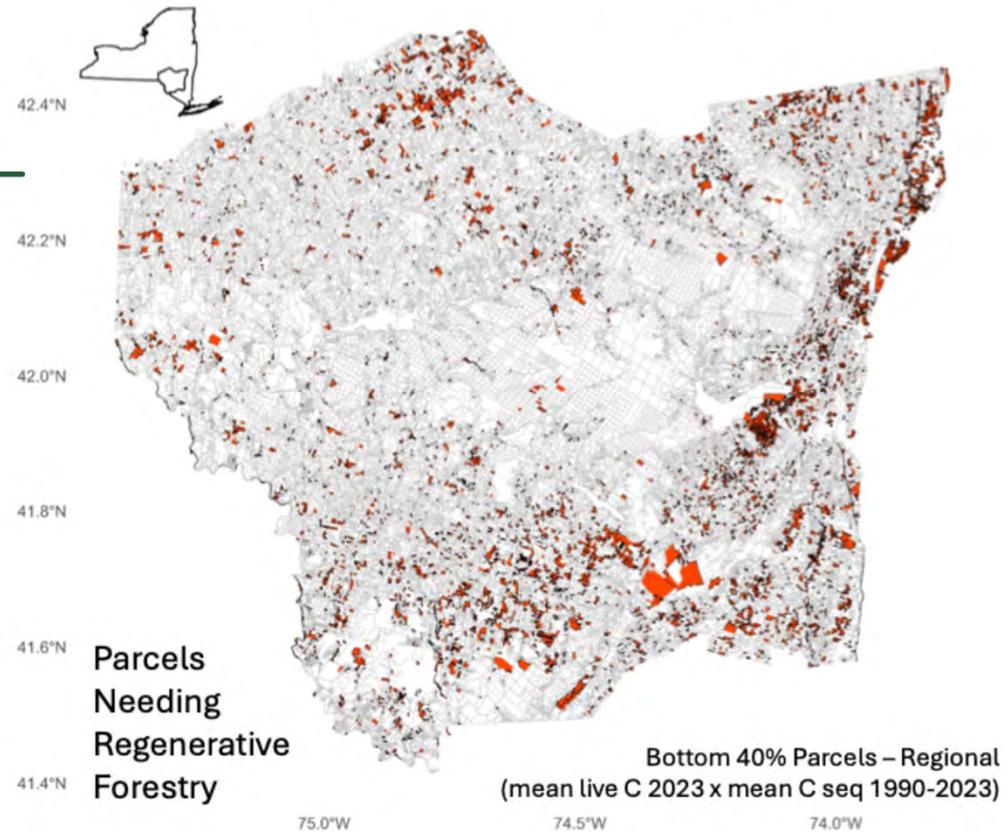

**Applications: Climate Solutions**

# Parcels

## Poorly Stocked & Slow Growing

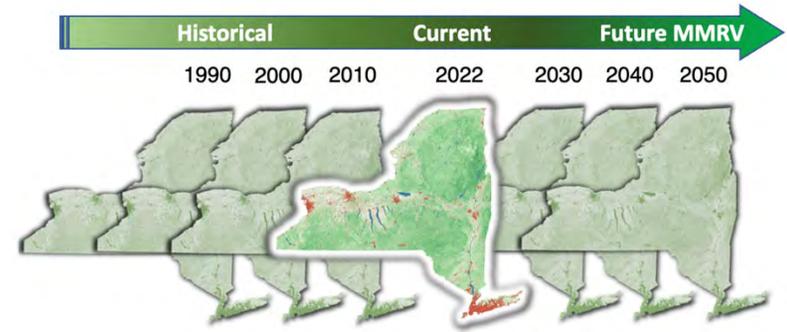

**Applications: Climate Solutions**

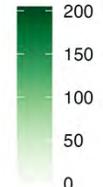

Target 1990

3 km

AGB (Mg/Ha)

LCPRI

Applications:  
marginal &  
transitional lands

Upstate NY is mostly a  
post-agricultural  
landscape

Old-fields in many areas  
are not going through  
succession as expected

Invasive shrubs are  
creating persistent  
shrub/scrub habitats

'Novel' ecosystems and  
cover types for NYS

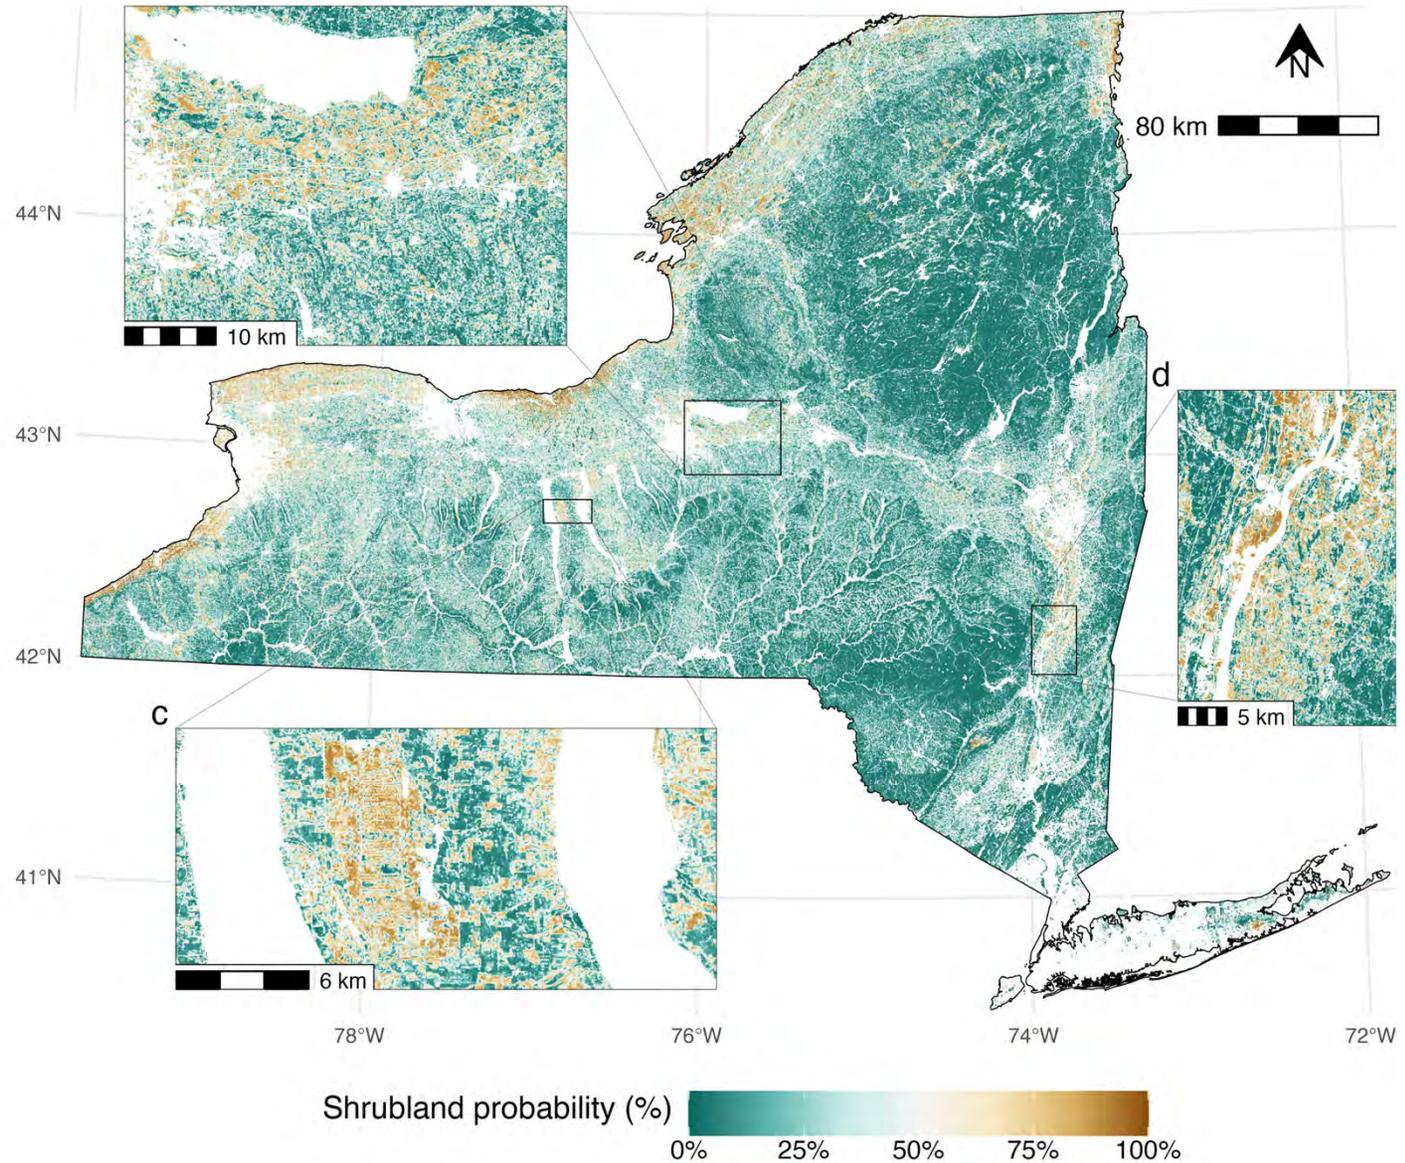

Applications:  
marginal &  
transitional lands

Combined LiDAR and  
Landsat to map low-statured  
vegetation (1-5m tall) at 30m

~1.4 million acres of  
'shrublands' across NYS

Long-term carbon benefits  
and co-benefits are limited  
relative to forests

Ideal sites for reforestation,  
bioenergy crops, solar/wind  
facilities, silvopasture, etc.

## Applications: urban forests & green spaces

We initially assumed  
that our LIDAR-AGB  
models would  
perform poorly in  
urban settings

A closer look  
suggests models can  
parse out built  
environment from  
urban tree cover

Neighborhood-scale  
assessment to  
support community-  
based planning and  
decision-making
